Is this a "Fast & Focused" Search Request? (Circle One) YES NO

A "Fast & Focused" Search is completed in 2-3 hours (maximum). The search must be on a very specific topic and meet certain criteria. The criteria are posted in EIC2100 and on the EIC2100 NPL Web Page at <http://ptoweb/patents/stic/stic-tc2100.htm>.

What is the topic, novelty, motivation, utility, or other specific details defining the desired focus of this search? Please include the concepts, synonyms, keywords, acronyms, definitions, strategies, and anything else that helps to describe the topic. Please attach a copy of the abstract, background, brief summary, pertinent claims and any citations of relevant art you have found.

Is this request for a BOARD of APPEALS case? (Circle One) YES NO

- Storing a first portion of a first database table and a first portion of a second database table on a first node, and storing a second portion of a first database table and a second portion of a second database table on a second node.
- generating a first join table from first portion of said first database table, and generating a second join table from a second said second portion of first database table.
- Comparing said first portion of said second database table with said first join table, and comparing said second portion of said second database table with said second join table to generate a first intermediate results file.

ABSTRACT EP 753819 A1

A system (10) and method enabling use of a COBOL compatible structured query language (CCSQL) to manipulate data stored in a COBOL data file (90), which is in a non-first normal, hierarchical format. Initially, a dictionary generator subsystem (68) creates a corresponding dictionary (74) for each COBOL data file (90). In the dictionary (74), the NF2) hierarchical logical relationship between the items and attributes (hierarchical nature) of each item of a COBOL data file are defined. Thereafter, whenever a new COBOL data file is produced, a corresponding dictionary is generated. When a user enters a request in the CCSQL format to query a COBOL data file, the request is parsed. The definitions in the dictionary are used by the CCSQL kernel (78) to manipulate the data in response to the user's query. A command interpreter (64) processes the request to determine the appropriate data manipulation to apply and initiates a CCSQL kernel request that carries out the intended action, with reference to the corresponding dictionary (74). For example, the request may require that certain items from a COBOL data file be extracted to produce a report (82). Because the hierarchical logical relationships between the items in the COBOL data are defined in the corresponding dictionary, a CCSQL report generator subsystem can produce the report using data extracted from the COBOL data file in accordance with criteria provided by the user, but without converting the data in the COBOL data files to a 1NF. COBOL programs with embedded CCSQL commands are preprocessed to convert the CCSQL commands to a COBOL compatible structured language that uses the dictionaries to access data referenced in the COBOL data files.

**English Abstract**

A method and apparatus for restricted access to a database according to user permissions are described. A user permissions file (1007) residing on a server includes information of permissions related to database records, and which of those permissions are associated with individual users. A permissions manager (1006) also residing on the server manages user queries (1002) either directly by generating restricted queries (1008) that reflect only authorized access to database records for the user generating the query, or indirectly by downloading a permissions filter or information for a restricted parameters screen to the user's client, so as to generate the restricted query (1008) on the client. In any case, a database management system (1001) residing on the server receives the restricted query (1008) and generates a result (1003) by accessing only authorized database records for the user, and communicates the result (1003) back to the user's client.

**French Abstract**

L'invention concerne un procede et un dispositif de restriction d'accès a une base de données en fonction d'autorisations utilisateur. Un fichier

d'autorisations utilisateur (1007) residant sur un serveur contient des informations d'autorisations liees a des donnees de base de donnees, lesdites autorisations etant associees a des utilisateurs individuels. Un gestionnaire d'autorisations (1006) residant egalement sur le serveur gere des requetes utilisateur (1002) de facon directe par production de requetes restreintes (1008) caracterisant uniquement l'accès autorise a des donnees de base de donnees pour l'utilisateur effectuant la requete, ou de facon indirecte par telechargement vers l'abonne d'un filtre d'autorisations ou d'informations concernant un crible de parametres restreints, de maniere a produire la requete restreinte (1008) au niveau de l'abonne. Dans tous les cas, un systeme de gestion de base de donnees (1001) residant sur le serveur recoit la requete restreinte (1008) et produit un resultat (1003) par acces a des donnees de base de donnees autorisees pour l'utilisateur, et retourne le resultat (1003) a l'abonne.

Detailed Description  
Claims

Fulltext Word Count: 19981

English Abstract

A data access system (100) and method provides platform independent access from a client module (101) to a variety of data sources (108) stored in a variety of data formats on a variety of computer systems, including database sources and electronic mail sources (112). The system includes a desktop client module (104) that is a Java applet (105) that runs within a Java-compliant browser (104) located on a client computer (101). The desktop client module provides access to any one of a plurality of data sources, each represented as a book (200) on the client desktop. Access of the data associated with a book is implemented using a data access service application running on a server computer (102) in communication with the desktop client. The data access service application (106) includes a data source interface (107) that stores metadata associated with each book. Accessed data is presented in a customized viewing format as (127) as specified by various views (204) and forms associated with each book.

French Abstract

L'invention concerne un systeme et un procede d'accès aux données qui permet d'avoir accès, indépendant de la plate-forme, depuis un module client, à diverses sources de données stockées sous diverses structures de données sur divers systemes informatiques, y compris des sources de

bases de donnees et des sources de courrier electronique. Ce systeme comprend un module bureau client qui est une mini-application Java tournant sur un navigateur compatible Java, situe sur un ordinateur client. Le module bureau client permet d'accéder a n'importe quelle source de donnees parmi plusieurs, chacune étant representee sous la forme d'un livre sur le bureau client. L'accès aux donnees associees a un livre se fait au moyen d'une application de services d'accès aux donnees tournant sur un ordinateur serveur en communication avec le bureau client. L'application de services d'accès aux donnees comprend une interface source de donnees qui stocke les metadonnees associees a chaque livre. Les donnees auxquelles on accede sont presentees dans un format d'affichage personnalise, tel que specifie par divers affichages et diverses formes associees a chaque livre.

...SPECIFICATION account when designing the tables in the database 121.  
In

the embodiment shown in Fig. 2, the database 121 comprises a single table with entries (records) comprising respective fingerprints and sets of metadata.

Another way to realize the database 121 is to set up several tables

. A first table comprises a plurality of unique identifiers (primary keys) each associated with respective sets of metadata. Such tables can be obtained from various music identification sources. The combination of artist, title and year of release could be combined to form a unique identifier, although this is not guaranteed to be unique, so preferably a really globally unique value...

...then set up with entries comprising for each multimedia object its fingerprint and its unique identifier from the first table. If multiple fingerprints are possible for one multimedia object, all these fingerprints are stored in the second table, all associated with the one unique identifier for that multimedia object.

The DBMS backend module 203 then matches the fingerprint computed by the fingerprinting module 202 against the fingerprints in the second table, obtains an identifier and matches the identifier against the first table to obtain the metadata. If the database 211 is an SQL database, the two tables could be "joined" (in SQL terms) on the identifier.

The DBMS backend module 203 feeds the results of the query to the response module...

...mobile phone, then the telephone number can be obtained through Caller

ID or Automatic Number Identification or similar means. The input module 201 then supplies the calling number to the response...

ABSTRACT EP 877327 A2

A computer implemented method for generating a response to a join.  
Two

tables are divided into fragments. A join fragment map identifies,  
for  
each respective fragment from the first table, the fragments from the  
second table which contain a record that satisfies the join predicate  
with a record from the respective fragment from the first table. The  
map

is used to eliminate fragments which cannot satisfy the join  
predicate.

SPECIFICATION

Background

The present invention relates generally to **database** systems, and more particularly to methods and apparatus for the processing of queries having join...

...in the same state as their residence. A join query must include at least

one **join** predicate to specify the criteria to select records from the two tables (e.g., that...

...of the customer be the same as the state in which the transaction occurred). A **join** query may also include one or more single-table predicates to select records from the individual tables.

To perform a **join** query, a conventional **database** system examines

every record in the second table for each record in the first table to

determine whether any records satisfy the **join** predicate. Such records

may be said to "match." The **database** system then constructs a query table from the matching records.

In many circumstances, conventional **database** operations may be unacceptably slow when performing a **join** query. Several techniques have

been developed to reduce the time required to process **join** queries. One

technique to improve the performance of a **join** query is to reduce the

amount of data searched by the **database** system. In particular,

records

that cannot satisfy the **join** predicate should be eliminated from both

tables of the query.

An example of such a...

... $r < 10$ ; ( Example 1)

This query attempts to find all records that satisfy the **join** predicate  $R.r = S.s$ .

Since records from Table R must also satisfy the predicate...

...since  $R.r$  must equal  $S.s$ , by applying the algebraic rule of transitivity, the **database** system can determine that matching records

of Table S must also satisfy the condition  $S.s < 10$ .

After deducing the predicate on S, the **database** system may apply the

predicate to eliminate records from the scan of S that cannot...

...records satisfy the criteria.

A 'scan' is the process of reading a fragment of a **table**.

Fragments

may be stored independently on separate disks or on separate nodes in a

cluster...

...Fragment elimination' is a process by which the database system can identify fragments from a **table** that cannot participate in the result

of the query and remove those fragments from consideration...network.

The computer system 10 includes a database 30 for storing and processing data. The **database** 30 may be centralized on a single computer, or it may be distributed across the computer network.

Typically, the **database** 30 will be managed by a **database**

management

system 38 running on a computer linked to the **database**, either permanently or transiently, although in this illustration the

**database**

management system is shown as running on the computer 12.

The invention will be illustrated using a **database** configured to store information for a credit card company. The **database** 30 is a relational **database** with a customer table ("Table R") 32 and a transaction **table** ("Table S") 34. In addition, the **database** 30 includes a **join** fragment map 36 bitmap (discussed below with

reference

to Figures 5-6). The **database** 30 may also include other resources, such

as rules for interacting and manipulating objects, index **tables**, and

interpreters to execute query requests (not shown).

Referring to Figure 2A, the customer **table** 32 includes a record

40

for each customer. Each record 40 includes a customer number...

...R.state) 46, and a credit card expiration month field (R.month) 48. The

customer **table** 32 is partitioned into twelve fragments, one for

each

expiration month. Each fragment contains records...

...59. The customer number fields 42 and 59 may be used as keys to link

**Table S** to **Table R**. For these illustrations, the transaction table

34 is

fragmented into fifty...fragments from **Table R** by applying known single-table techniques.

To eliminate other fragments, the **database** system generates or accesses the **join** fragment map 36. The **join** fragment map 36

indicates

which fragments from the two tables do not contain records which can satisfy the **join** predicate and need not be searched during the

query

execution. Thus, the **join** fragment map is specific both to the content

of the **database** and the **join** predicate. If the content of the **database** changes, the **join** fragment map may become invalid. The

**join**

fragment table 36 may be stored as a bitmap, as multiple field-fragment maps, or...

...structure that indicates which pairs of fragments do not contain records

that can satisfy the **join** predicate. The **join** fragment map may be composed from two field-fragment maps 60 and 70 (see Figures 3A and

3B)

for the two tables in the query. The **join** fragment map may be implemented in a **database** system using a relational, hierarchical, object-oriented, or non-relational **database**.

Referring to Figure 3B, the database system 30 generates or accesses a

field-fragment map...

...match the state. For example, field-fragment map 70 includes a list of

fragments from **Table S** that contain records with **S.state** = "CA", a list

of fragments that contain records...

...3A, the database system 30 generates or accesses a similar field-fragment map 60 for **Table R**. The field-fragment map 60 also includes an entry 62 for each state. Each entry 62 matches a

particular

state 64 to a list 66 of fragments from **Table R** that contain records

that match the particular state. There should be fifty entries 62...

...66 will contain at most twelve fragment numbers because there are only

twelve fragments in **Table R**.

Referring to Figures 3A and 3B, by reading the first row of the field-fragment maps 60 and 70 together, the **database** system may determine that some records from certain fragment numbers (4, 5, 9 and

12) of **Table R** will match some records from certain fragment numbers

(2, 4, 7, 27 and 39) of **Table S**. Similarly, by reading from the

second

row of each map, the **database** system may determine that records from certain fragment numbers (1, 2, 7, 9 and 11) of **Table R** will match records from certain fragment numbers (5, 7, 27, 30, 31 and 45) of **Table S**.

Referring to Figure 4, the **join** fragment map may be composed of a single fragment-fragment map 80, formed by combining...

...the state columns 64 and 74 from the two field-fragment maps. The fragment-fragment **join** map 80 will contain twelve entries 82, i.e.,

one entry for each fragment of **Table R**. Each entry 82 will include a list of fragment numbers from **Table S** that contain records that satisfy join predicate with records from the associated fragment 84 of **Table R**.

For example, the first entry has a list of fragments (5, 7, 27, 30, 31, 45) from **Table S** that contain records that satisfy the join predicate with one or more records from...

...bit (shown as shaded in the Figure) denotes that some record in the fragment of **Table S** will join with the corresponding fragment of **Table R**. The bitmap 90 may be...

...only six fragments of **Table S** need be scanned.

Similarly, if the record fetched from **Table R** is from fragment #12, then

only five fragments from **Table S** need be scanned, namely fragments #2,

#4, #7, #27 and #39.

The creation of...

...A user can explicitly create a bitmap using the data definition language

for a given **database** in similar fashion to the creation of an index.

The **database** system can implicitly create a bitmap when a foreign key

relationship is specified as an integrity constraint. The system can exhaustively search for **joins** between **tables** that yield sparse bitmaps.

In all of these cases, the system can use sampling to...

...the percentage of bits that are turned on in a bitmap indicating fragments from two **tables** that have matching tuples.

To generate (or build) the bitmap 90, the **database** system executes a

'simplified query' based on the original query. The simplified query contains the same **join** predicate as the original query, but none of the

single-**table** predicates. For example, the simplified query for the query of Example 3 is:

SELECT R...

...S.state (Example 4)

Executing the simplified query returns the corresponding fragment numbers from each **table** that contain matching records. The bitmap 90

may be generated directly, without generating the intermediate **join** map

80 described above. Various techniques may be used to increase the speed

with which...

...query is executed. Preferably, the necessary fields of the records from

the first or second **table** are retrieved from the leaves of a **table** index rather than from the **table** itself. In addition, column indices

can be used, if they exist. As another example, information...

...of the simplified query, once a match has been made between fragments

from the two **tables**, other records need not be searched for the same

match.

The creation of a bitmap...

...too full, i.e., non-sparse, indicating that records from a fragment of

the first **table** have corresponding matching records in a large percentage of the fragments from the second table...bitmap B2) can be used to eliminate fragments from Table R again. In general, the **database**

system would begin by using single-table fragment elimination to eliminate fragments from Tables R...

...bitmap B2 is used against Table S to eliminate fragments in Table T.

Then the **database** system uses the newly eliminated fragments in Table T

to reduce Table S again, and...

...it uses the newly eliminated fragments in Table S to reduce Table R again. The **database** system continues to repeat this procedure until no

more fragments can be eliminated from any table.

The **database** system should pick the former procedure if **join** queries between **Tables** R and T are common since that procedure results

in generating bitmap B3 (without explicitly...

...simplified bitmap query") which can be stored and used later. On the other hand, the **database** system should pick the latter procedure if the

**join** queries between **Tables** R and T are relatively rare and do not

warrant the overhead of maintaining bitmap B3.

Since the **join** fragment map is generated from the result of an actual

**join** query, i.e., since the map depends upon the actual data in the **tables**, its usefulness is diminished or even destroyed when the underlying **tables** are modified.

If records have been deleted from one or both **tables**, the bitmap can

still be used. Performance may be less than ideal as the **database** system may search fragments that no longer have matching records.

If records have been added or updated in one or both **tables**, the integrity of the bitmap may be destroyed. If the added or modified value

now...the bitmap as invalid if data modification occurs to one or both of

the underlying **tables** which invalidates the previous bitmap. The executor 200 uses the bitmap to perform dynamic co...no additional fragments were marked as inactive from Table R, then in step 136 the **database** system returns to the optimizer rather than proceeding to the

subroutine 140 to optimize Table...

...172). A simplified query is then constructed (step 174). The simplified

query contains the same **join** predicate as the query presented by the

user, but all single-table predicates are removed...

...the dictionary manager subroutine 190 is called (step 180), the locks

are released, and the **database** system returns to the optimizer (step 182).

Referring to Figure 12, the dictionary manager 190 begins by determining whether a previous bitmap has been created for the **join** predicate of the current query (step 192). If a previous bitmap exists, then the old...

...this query, then the step of discarding the previous bitmap may be skipped. Finally, the **database** system returns to the bitmap generator subroutine (step 198).

Referring to Figure 13, executor 200 is called when the **database** system executes the **join** query in step 106 (see Figure 7). In brief,

the executor receives a record from...

...although Tables R and S could be switched in the operations discussed

below. Then the **database** system uses the **join** fragment map to identify the fragments of Table S that should be scanned for matching records (step 204). Specifically, if the **join** fragment map is a bitmap,

the **database** system accesses the bit at a row equal to the fragment number of Table R and a column equal to the fragment number of Table S

to determine whether that pair of fragments contain records which satisfy

the **join** predicate. The identified fragments of Table S are scanned

for records that satisfy the join predicate (step 206). These records are collected (step 208) and returned to the user (step...

...200 can be carried out in a looped process in which each active fragment from Table S is examined, the bitmap is used to determine whether the fragment should be scanned...

...CLAIMS preceding claim, further comprising the steps of receiving or accessing a record from the first table ; and scanning the identified fragments for records that satisfy the join predicate with the received record.

12. A method as claimed in claim 11, further comprising the step of selecting a fragment containing a record which satisfies the join predicate.

13. A method as claimed in any preceding claim, wherein the join query is intended to be executed in relational database tables which are separable into fragments.

14. A method as claimed in any preceding claim, wherein the step of creating comprises executing a simplified query having at least part of the join predicate.

15. A method as claimed in any preceding claim, wherein the join fragment map is a bitmap having a bit for each pair of fragments of the first and second tables and the method comprise the step of creating the bitmap having a bit for each pair of fragments of the first and second tables .

16. A method as claimed in claim 15, further comprising the steps of determining whether...

ABSTRACT EP 490465 A2

A relational data access facility allows relation-type queries to  
access data stored in non-relational data files by converting  
relational

queries into a set of common commands which are sent to data drivers to obtain the data specified by those queries. The facility uses metadata which describes the organization of the data in the non-relational files, and examines the expressions in the relational queries to formulate an access plan for the data. The plan is formulated to reduce cost and promote efficiency. (see image in original document)

English Abstract

A method and apparatus for restricted access to a database according  
to

user permissions are described. A user permissions file (1007)  
residing

on a server includes information of permissions related to database  
records, and which of those permissions are associated with  
individual

users. A permissions manager (1006) also residing on the server manages user queries (1002) either directly by generating restricted queries (1008) that reflect only authorized access to database records for the user generating the query, or indirectly by downloading a permissions filter or information for a restricted parameters screen to the user's client, so as to generate the restricted query (1008) on the client. In any case, a database management system (1001) residing on the server receives the restricted query (1008) and generates a result (1003) by accessing only authorized database records for the user, and communicates the result (1003) back to the user's client.

#### French Abstract

L'invention concerne un procede et un dispositif de restriction d'accès a une base de données en fonction d'autorisations utilisateur. Un fichier d'autorisations utilisateur (1007) residant sur un serveur contient des informations d'autorisations liees a des données de base de données, lesdites autorisations étant associees a des utilisateurs individuels. Un gestionnaire d'autorisations (1006) residant également sur le serveur gere des requetes utilisateur (1002) de facon directe par production de requetes restreintes (1008) caracterisant uniquement l'accès autorisé a des données de base de données pour l'utilisateur effectuant la requete, ou de facon indirecte par telechargement vers l'abonné d'un filtre d'autorisations ou d'informations concernant un crible de paramètres restreints, de maniere a produire la requete restreinte (1008) au niveau de l'abonné. Dans tous les cas, un systeme de gestion de base de données (1001) residant sur le serveur recoit la requete restreinte (1008) et produit un resultat (1003) par accès a des données de base de données autorisees pour l'utilisateur, et retourne le resultat (1003) a l'abonné.

#### Detailed Description

... viewincludes information, for example, only for DEVICE1, DEVICE2 or DEVICE3. In particular, for the PRODUCTION table of FIG. 7, three views are created.

```
CREATE VIEW PRODUCTION1 AS SELECT *  
FROM PRODUCTION  
WHERE...  
...this case.
```

Although the methods and apparatuses described in reference to FIGS. 4-6 provide **database** security, they have numerous problems. For example, they are cumbersome to  
3  
implement, because of...

...maintain, because of the large number of items to be updated as the amount of **database** information grows larger. Further, such techniques may fail their primary purpose of **database** security when a join graph automatically generated for a query includes additional tables that are not otherwise protected from...

...an object of the present invention to provide a method for restricting access to a **database** according to user permissions, that is easy to implement and simple to maintain.

Another object is to provide an apparatus for restricting access to a **database** according to user permissions, that is easy to implement and simple to maintain.

Still other objects are to provide a method and an apparatus for restricting access to a **database** according to user permissions, that do not fail their primary purpose of **database** security as a result of the inclusion of additional tables not specified in the original query that are added through a join graph for the query.

These and additional objects are accomplished by the various aspects of  
...

...present invention, wherein briefly stated, one aspect is a method for restricting access to a **database** according to user permissions, comprising: receiving a user identification provided by a client user; receiving a query provided by the client user for a **database**; and generating a restricted query to be provided as input to a **database** management system for the **database** by adding one or more restrictions to the query according to permissions associated with the user identification so as to restrict access to the **database**.

Still another aspect is an apparatus for restricting access to a

**database** according to user permissions, comprising a server computer configured to: receive a user identification from...  
...database management system for accessing a database in response to a restricted query; user permissions **file** including information associating users with database records accessible to those users; and  
permissions manager generating...

...list of tables involved in the query. Continuing with the example, the first list of **tables** in the above query is I WAFERS 1.

In 1504, a Est of permissions for...

...to form a merged list of tables.

Continuing with the example, the merged list of **tables** in this case is  
I WAFERS, PRODUCTION1.

In 1506, **joining** requirements for the merged list of **tables** are satisfied, resulting in a final list of **tables** including those necessary to complete a **join** graph including the merged Est of **tables**

. U.S. Patent Application Ser. No. 09/871,484 entitled "Automatic Generation of **Join** Graphs for Relational **Database** Queries,"  
**filed**

May 31, 2001, assigned to the same assignee as the present application,  
and incorporated herein...

...this reference, describes one method for performing this function.  
Now,

continuing with the example, the **join** procedure adds the **table** LOTS,  
so that the final list of **tables** is I WAFERS, PRODUCTION, LOTS1.  
Additional join conditions necessary to complete the join graph include.

10  
PRODUCTION.DEVICE=LOTS.DEVICE, and  
LOTS.LOT=WAFERS.LOT.

In 1507, the final list of **tables** is used to replace the "FROM" list  
in. the query.

Continuing with the example, replacing...

...LOT='A1.

In 1508, the "WHERE" list of the query is modified to include any **join**  
conditions that are missing, but should be included. Also, additional restrictions are added to the...

...granted to the client user that restrict the user's access to records of

the **database** . Again continuing with the example, adding the **join** conditions in the WHERE clause results in the modified query.

SELECT WAFERS.LOT, WAFERS.WAFER...

Claim

... a WHERE clause, and said modifying said query comprises modifying said

FROM clause to include **tables** required by said permissions associated with said user identification.

5 The method according to claim 4, wherein said modifying said query further comprises modifying said WHERE clause to include **join** conditions resulting from including said **tables** required by said permissions associated with said user identification in said FROM clause.

6 An apparatus for restricting access to a **database** according to user

permissions,

comprising a server computer configured to:

receive a user identification from a client computer;

receive a query from said client computer for a **database** ; and

generate a restricted query to be provided as input to a **database** management system for said **database** by adding one or more

restrictions

to said query according to permissions associated with said user identification so as to restrict access to said **database** .

7 The apparatus according to claim 6, wherein said server computer is configured to generate...

...server computer is configured to modify said query by modifying said FROM clause to include **tables** required by said permissions associated with said user identification.

10 The apparatus according to claim...

...computer is further configure to modify said query by modifying said WHERE clause to include **join** conditions resulting from including said

**tables** required by said permissions associated with said user identification in said FROM clause. It. An apparatus for restricting access to a **database** according to user permissions, comprising a server computer including:

**database** management system for accessing a **database** in response to a

restricted query; user permissions **file** including information associating users with **database** records

accessible to those users; and

permissions manager generating said restricted query according to

said

information included in said user permissions **file** in response to a query from an identified user, and

providing said restricted query to said **database** management system.

12 The apparatus according to claim 1 1, wherein said server computer is

...

...on said client computer so that said user interface displays said available options limited by **tables** , columns and records accessible to said user on a display screen of said client computer...

...joining of said merged set of tables.

38 An apparatus for restricting access to a **database** according to user permissions, comprising a computer configured to receive a user identification provided by a user of a client computer; receive a **database** query including a SELECT clause, FROM clause, and WHERE clause provided by said user; and modify said WHERE clause of said **database** query to include permissions associated with said user identification that restrict access by said user to only authorized **database** records in a **database** .

39 The apparatus according to claim 38, wherein said computer is further configured to: extract a first set of tables associated with said **database** query by parsing said **database** query; extract a second set of tables from said permissions associated with said user identification that restrict access by said user to only authorized **database** records in said **database** ; merge said first set of tables and said second set of tables to generate a...

...tables and said merged set of tables; and modify said WHERE clause to include additional **join** conditions as necessary for **joining** of said merged set of tables.

40 A method for restricting access to a **database** according to user permissions, comprising: generating information of permissions related to **database** records; and generating information of users and associated permissions from said information of permissions so that access to said **database** records is restricted according to said information of users and associated permissions.

41 A method for restricting access to a **database** according to user permissions, comprising providing a computer executable program including program code for facilitating generation of information of permissions related to **database** records, and generation of information of users and associated permissions from said information of permissions...

**English Abstract**

A method of comparing two source files containing database queries is  
described in which the database queries are ascertained from the two  
source files and in which the ascertained database queries from a  
first

source file are compared with the ascertained database queries of a  
second source file. A quick and efficient analysis of different  
program

versions is achieved by ascertaining the syntax of each database  
query

with the help of a syntax analysis, by comparing the syntax of the  
database queries of the source files with one another and by  
presenting

the results of the comparison.

#### French Abstract

L'invention concerne un procede permettant de comparer deux fichiers source contenant des demandes de base de donnees, lesquelles demandes sont determinees a partir des deux fichiers source dans lesquels les demandes determinees provenant d'un premier fichier source sont comparees

aux demandes de base de donnees determinees d'un second fichier source.

Une analyse rapide et efficace de differentes versions de programme est

realisee par determination de la syntaxe de chaque demande de base de donnees au moyen d'une analyse de syntaxe par comparaison de la syntaxe

des demandes de base de donnees des fichiers source avec une autre et par

presentation des resultats de la comparaison.

#### Detailed Description

COMPARISON OF SOURCE FILES

FIELD OF THE INVENTION

[0001] The present invention relates to a method of comparing two source

...

...a comparison device comprising a reader for reading source files and an

extractor for extracting database queries from source files .

#### BACKGROUND OF THE INVENTION

[0002] Database queries from external sources are coded to access databases , particularly relational databases such as IBM's DB2.

The

coded query text of a database query

comprises different elements. Database queries are carried out through

a standardized interface, the Structured Query Language (SQL) interface.

Here SQL queries are transmitted to the database system and

processed  
by the **database** system.

These SQL queries can consist of a number of query elements, whereby,  
for  
example,  
the elements "CursorName", "StatementType" (Select, Insert, Update, Delete),  
" **Tables** ", " **Join** .s", "Predicates", "Select, Update and Insert  
Columns", "Select Option Text" and "Select Option Columns" can be  
used.

[0003] On a query of a **database** using SQL, actions are triggered  
in  
the  
**database** system that enable the **database** query to be answered.  
The  
response times for **database** queries can vary greatly depending  
on the  
query elements that are coded. It is desired...

...possible response times.

#### CONFIRMATION COPY

[0004] Programs that work with the data records of the **databases**  
are  
changed over the course of time. A change in the SQL queries can  
accompany...

#### Claim

1 A method of comparing a first source file with a second source  
file,  
said **first**  
and second source files each comprising one or several database  
queries,  
wherein said database queries are ascertained from said first and  
**second**  
source **files** and wherein the ascertained **database** queries of  
said  
first source **file** are **compared** with the **ascertained database**  
queries of said **second** source **file** ,  
which method comprises:  
performing a syntax analysis to **ascertain** a syntax of each of said  
database  
queries;  
performing a comparison of said syntax of...

...and  
presenting the results of said comparison.

2 The method of claim 1, wherein each **database** query of the first  
source **file** is combined with each **database** query of the **second**  
source **file** to form combined  
database queries.

3 The method of claim 1 or 2, wherein said...

...each syntactical element and -wherein the weighted difference  
between

the syntactical elements of the combined **database** queries is used  
to  
determine the similarity  
value with the help of said weightso

ABSTRACTED-PUB-NO: EP 1353278A

BASIC-ABSTRACT:

NOVELTY - Method for comparison of two source files containing database queries, in which the two database queries are extracted from the source files and compared. Accordingly the syntax of each query is analyzed using syntax analysis tools, then the syntax of the database queries are compared

with each  
other and the results of the comparison are output.

USE - Method for comparison of database queries, e.g. for comparison  
of queries  
generated using different database languages, programs or versions of  
the same  
language or program.

ADVANTAGE - Differences between two program versions can be quickly  
and  
reliably determined, so that possible problems can be prevented.

DESCRIPTION OF DRAWING(S) - The figure shows a flow diagram of an  
inventive  
method.

**English Abstract**

A replicating plant (110) receives a master recording (102)  
comprising a

number of tracks from a content producer (101). The audio  
fingerprints of

the tracks are computed and submitted to a verifying server (120).

The

server performs a database lookup to identify the tracks based on the  
submitted fingerprints. The list with identified tracks is then  
compared

against authoritative lists (103) submitted by content providers (101).  
If a match is found, the verifying server (120) transmits a positive response to the replicating plant (110), otherwise it transmits a negative response. Preferably the response is digitally signed to allow the replicating plant (110) to verify its authenticity. The response may include the matching authoritative track list, so that the replicating plant (110) also obtains accurate metadata for the tracks. This metadata could then be included in the replicated copies (112).

#### French Abstract

L'invention concerne une installation de replication (110) recevant un enregistrement principal (102) comprenant un certain nombre de pistes, a partir d'un dispositif de production de contenu (101). Les empreintes audio des pistes sont calculees et soumises a un serveur de verification (120). Le serveur effectue une verification de base de donnees pour identifier les pistes en fonction des empreintes soumises. La liste contenant des pistes identifiees est ensuite comparee a des listes faisant autorite (103), soumises par des fournisseurs de contenu (101).  
Si une correspondance est trouvee, le serveur de verification (120) transmet une reponse positive a l'installation de replication (110), sinon il transmet une reponse negative. De preference, la reponse est numeriquement signee pour permettre a l'installation de replication (110) d'en verifier l'authenticite. La reponse peut comprendre la liste de pistes faisant autorite correspondante de sorte que l'installation de replication (110) obtienne egalement des metadonnees precises pour les pistes. Ces metadonnees peuvent ensuite etre comprises dans des copies repliquees (112).

English Abstract

A method and system for adding real-time, interactive functionality  
to a

web-page, e.g., a HTML document, that enables interaction between and

among a plurality of users viewing the same web-page. Software stored on and operable in connection with a server computer (40) comprises a server component (400) and a client component (300). The server component provides general server functionality and proxy server functionality on the server. The client component is downloadable by the server for storage on and operation in connection with one or more client computer (10, 20), and adds real-time, interactive functionality to a web-page.

#### French Abstract

L'invention concerne un procede et un systeme d'ajout d'une fonctionnalite interactive en temps reel a une page Web, par exemple, un document HTML, qui assurent l'interaction entre une pluralite d'utilisateurs visualisant la meme page Web. Un logiciel enregistre dans un ordinateur serveur (40) et exploitable a partir de ce dernier comprend une composante serveur (400) et une composante client (300). La composante serveur assure une fonctionnalite serveur generale et une fonctionnalite serveur mandataire dans le serveur. La composante client peut etre telechargee par le serveur en vue de son stockage et son exploitation par un ou plusieurs ordinateurs client (10, 20), et permet d'ajouter une fonctionnalite interactive en temps reel a la page Web.

English Abstract

The present disclosure relates to a system and method for improved  
data

(or information) storage, control and/or access (fig. 1). A

system/method

according to the disclosure facilitates enhanced versioning of data files

(fig. 3), data records (fig. 5) information (fig. 6) and the like, such

that subsequent data file and/or record retrieval is consistent with and

reflective of ancillary conditions at the time of the data file and/or

record input (fig. 7). The system/method provides enhanced data/information storage, control and access that have applicability in a

variety of fields (fig. 5), including applications related to health care, mental health care, financial and accounting systems,

industrial

control systems, and the like (fig 7L).

#### French Abstract

Cette invention concerne un systeme et un procede ameliorant le stockage,

le controle et/ou la consultation de donnees (ou informations). Selon cette invention, ce systeme/procede permet de simplifier un controle de

versions renforce de fichiers de donnees, de fiches, d'informations ou

analogue, de maniere qu'une extraction ulterieure de fichiers de donnees

et/ou de fiches soit coherente et refilete des conditions auxiliaires au

moment de l'entree du fichier de donnees et/ou de la fiche. Ce systeme/procede permet un renforcement du stockage, du controle et de la

consultation de donnees/d'informations pouvant etre appliquees dans une

multitude de domaines, y compris dans des applications relatives aux soins de sante, aux soins de sante mentale, aux systemes financiers et

comptables, aux systemes de controle industriels et analogue.

English Abstract

A data access system (100) and method provides platform independent  
access from a client module (101) to a variety of data sources (108)  
stored in a variety of data formats on a variety of computer systems,  
including database sources and electronic mail sources (112). The  
system

includes a desktop client module (104) that is a Java applet (105)  
that

runs within a Java-compliant browser (104) located on a client  
computer

(101). The desktop client module provides access to any one of a plurality of data sources, each represented as a book (200) on the client desktop. Access of the data associated with a book is implemented using a data access service application running on a server computer (102) in communication with the desktop client. The data access service application (106) includes a data source interface (107) that stores metadata associated with each book. Accessed data is presented in a customized viewing format as (127) as specified by various views (204) and forms associated with each book.

#### French Abstract

L'invention concerne un systeme et un procede d'accès aux données qui permet d'avoir accès, independant de la plate-forme, depuis un module client, a diverses sources de données stockees sous diverses structures de données sur divers systemes informatiques, y compris des sources de bases de données et des sources de courrier electronique. Ce systeme comprend un module bureau client qui est une mini-application Java tournant sur un navigateur compatible Java, situe sur un ordinateur client. Le module bureau client permet d'accéder a n'importe quelle source de données parmi plusieurs, chacune étant representee sous la forme d'un livre sur le bureau client. L'accès aux données associees a un livre se fait au moyen d'une application de services d'accès aux données tournant sur un ordinateur serveur en communication avec le bureau client. L'application de services d'accès aux données comprend une interface source de données qui stocke les metadonnées associees a chaque livre. Les données auxquelles on accede sont presentees dans un format d'affichage personnalise, tel que specifie par divers affichages et diverses formes associees a chaque livre.

Detailed Description  
Claims

Fulltext Word Count: 10702

**English Abstract**

A method and apparatus for displaying structured information such as information that is stored in plural interrelated tables (110, 120, 130, 140, 150, 160, 170, 180). A structural map (13) that describes that pathing between the interrelated tables (110, 120, 130, 140, 150, 160, 170, 180, 190) is defined. The structural map (13) may be a computer representation of a multiple index multipartite graph which defines that structure of the structured information (12). A display map (14) is defined for describing how to display the information. The display map (14) describes where the information from the tables is to be displayed, and where, rather than displaying information from the tables, information concerning the structural interrelationship of the tables (110, 120, 130, 140, 150, 160, 170, 180, 190) is to be displayed. In response to a query based interaction with an operator (20), either information from the plural tables is displayed or an indication of further structure is displayed. When information is displayed it is filtered by the previous level of structure indexed by the information targeted by the operator (20) such that only information of concern to the operator's query is displayed. The display may be in the form of

pop-down windows (17) and those windows may contain mixed data and structural information (16a, 16b), or the display may be in the form of

graphs having nodes and paths (13, 14). Displayed information may be modified and the modifications are traced through the structured information (12) so as to allow dynamic display of modified data (15).

#### French Abstract

Un procede et un appareil permettent d'afficher des informations structurees telles que celles stockees dans plusieurs tables liees entre

elles (110, 120, 130, 140, 150, 160, 170, 180). On definit une carte structurelle (13) qui decrit les chemins reliant ces tables (110, 120,

130, 140, 150, 160, 170, 180, 190) et qui peut etre une representation

informatique d'un graphique multipartite a index multiples definissant

cette structure des informations structurees (12). On definit une carte

d'affichage (14) qui indique comment afficher les informations et decrit

l'endroit ou les informations provenant des tableaux doivent etre affichees et celui ou il s'agit au contraire d'afficher des informations

concernant les relations structurelles des tables (110, 120, 130, 140,

150, 160, 170, 180, 190). En reponse a une interaction basee sur une requete avec un utilisateur (20), on voit s'afficher soit des informations provenant des tables soit une indication complementaire concernant leur structure. Si des informations sont affichees, elles sont

filtrees par le niveau precedent de structure indexee selon les informations souhaitees par l'utilisateur (20) de facon que seules sont

affichees celles repondant a sa requete. Cet affichage peut prendre la

forme de fenetres a incrustation (17) pouvant contenir un melange de donnees et d'informations structurelles (16a, 16b) ou bien il peut prendre celle de graphiques dotes de noeuds et de chemins (13, 14).

On

peut modifier les informations affichees et ces modifications apparaissent dans les informations structurees (12), ce qui permet un affichage dynamique des donnees modifiees (15).

#### Fulltext Availability:

Detailed Description

#### Detailed Description

... of interrelationships in the structured information increases, the complexity of the structure increases and many **tables** (or partitions) may be used to store the information.

For example, in the situation where...  
...the-tables is only a subset of the

total amount of information in the relational **database** , In the above example, a first table in the relational **database** might be a student table consisting of student name, identification number, dormitory assignments, etc.; and a second table in the relational **database** might be a course table consisting of course name, prerequisites, class time, place, etc, The...

...third, intermediary table is created which cross-references students to courses, This, then, provides two **join** fields, the student and the course, which together give the cross-reference of student-to-course.

The individual tables in a relational **database** are normally linked with one another through " **join** fields". In the above example, the **join** fields were the student identification number and the course number, Such a field links or **joins** the tables in the **database** . To correlate the information in a first table with the information in a second table, first the **join** field is extracted from the first table, Next, the **join** field is indexed to the second table by which it can be determined which entries in the two tables are associated, Usually, the indexing is via an intermediary, cross-reference, **table** (e.g., in "many-to-manyll situations) but where an entry is **joined** directly into a **table** (e.g., a "many-to-onell situation) there is usually no need for an intermediate **table** .

Relational **databases** are effective to break complexly structured information into comprehensible and manageable units. Nevertheless, as the of information is normally available in a separate **table** in a relational **database** , but owing to the complexity of the interrelationships between those **tables** , it has not heretofore been practical to correlate that information and to display it in useable form.. Or to consider the problem of adding or deleting a course. The course **joins** with the teachers giving the course, the usage of facilities, books, students taking courses, schedules...such as by changing, adding

or deleting information, The appropriate one of the plural interrelated **tables** is updated based on the edit, In the case of deletion, dangling **joins** are deleted, preferably under operator supervision; in the case of additions, new **joins** are created.

For example, a classical **database** problem concerns finding and deleting or moving data that is very active or very inactive, If a **database** /graph

includes historical footprints of usage (like timestamping), then the invention can filter and order...as a supervisory terminal having special privileges with respect to altering the contents of the **tables** in memory 12, In such a case, others of the plural terminals would only be...stored on disks

16a

and

16b. Typically, each of the tables have at least one **join** field which links that table to at least one other table in memory 12, Usually, each table further includes at least one **join** field which allows it to be linked with other tables in the **database** . The two **join** fields may be the same field in which case the table is accessed by the...

...which it accesses other tables.

It is possible for there to be more than one **join** field in each table so as to permit a table to be linked in different ways with different tables, and it is also possible for a table to be **joined** to several other tables, Various **join** configurations yield many different structural possibilities. For example, many tables can **join** into one table ("many-to-one"); one table can include many **join** fields that branch out to many other tables ("one-to-many"); or many **tables** can join into one **table** which in turn joins into many other **tables** ("many-to-many"), All these structural possibilities create a variety of paths and multidimensionalities in the multipartite graph represented by the **tables** .

The structural map stored in memory 13 is dependent upon both the structure of the interrelationships in the **tables** and the organization of information in the individual **tables** , The structural maps may be derived automatically by the CPU but typically are prepared manually based on the overall structure and interrelationship of the **tables** ,

The display maps stored in memory 14 define the information that is to be displayed...the difference in the

windows definition from

- 34

Figure 7, the pathing through the information **tables** is different than that in Figure 11 and therefore results in different information in the displays.

For example, as shown in Figure 14, which shows pathing through the **tables** , the doctors from the md master **table** 110 that are displayed in Figure 13 are filtered through the targeted department from the department **table** 150 and the targeted times group from the times group **table** 120, Because these

filters are ordered differently than in Figure 12, however, the ultimate information...

...been utilized to present structured information to the operator, But a graphic representation of the **database** is also usable for viewing structure, adding paths, deleting paths, and deleting data and associated...information needed to display and manipulate the graph itself, The TableEquivDef sections show groups of **database table** names and index names that are equivalent, i.e., that are **joins**, This implicitly indicates those **tables** that are **joined** together. The ScreenNodeDef section shows information about the root **database tables**, i.e., those **tables** which have partition nodes as indices.

The information includes a screen Title in quotation marks...

...description of how the node values should be shown on the screen, For example, the **table** mdmaster is such a **table**; it will be referred to on the screen as "doctors", The index which defines nodes is mdnum in the mdmaster **table**; and the screen representation of each node value will be one character from md-Fname...

English Abstract

A method of improving network database performance is disclosed (Fig.  
1).

The method comprises steps of determining whether a first network  
packet

involves a database transaction (14) and then intercepting the packet upon a positive determination. The packet is then examined to determine the nature of the database transaction (18). Depending on the nature of the database transaction, a database acceleration technique is selectively implemented (22).

#### French Abstract

L'invention concerne un procede d'amelioration des performances d'une base de donnees en reseau (Fig. 1). Ledit procede comprend les etapes suivantes : determiner si un premier paquet de reseau implique une transaction (14) de base de donnees, et intercepter le paquet lors d'une determination positive. Ledit paquet est alors examine aux fins de la determination de la nature de la transaction (18) de base de donnees. Selon la nature de ladite transaction de base de donnees, une technique d'acceleration de base de donnee est mise en oeuvre (22) de maniere selective.

English Abstract

A link lock system for a network is disclosed. The system includes a  
computer, a network interface device, a bus monitor, and a security  
switch. The network interface device provides the computer with  
access to

the network. The bus monitor monitors a link between the network  
interface device and the computer. The bus monitor reports detected  
failures or intrusions. The security switch switches the link from a  
non-secured mode to a secured mode when a report of said detected  
failures or intrusions is received from the bus monitor.

French Abstract

L'invention concerne un systeme de verrouillage de liaison pour  
reseau.

Le systeme comprend un ordinateur, un dispositif d'interface de

reseau,  
un moniteur de bus et un commutateur de securite. Le dispositif  
d'interface de reseau permet a l'ordinateur d'accéder au reseau. Le  
moniteur de bus surveille une liaison entre le dispositif d'interface  
de  
reseau et l'ordinateur. Le moniteur de bus signale defaillances ou  
intrusions. Le commutateur de securite fait passer la liaison d'un  
mode  
non securise a un mode securise lors de la reception, par le moniteur  
de  
bus, d'un rapport signalant une defaillance ou une intrusion  
detectee.

Detailed Description

Claims

Fulltext Word Count: 2514

English Abstract

The response time from a client on a network is measured and a destination address is selected based on the measured response time.

The

client requests an address from the network. The network may be a local

network or a wide area network such as the Internet. The response time of

the client is measured to determine the optimum speed at which the client

may operate. The measured response time is communicated to the server,

where a destination address is selected based on the requested address

and the measured response time. The client may then be connected to

the

destination address.

French Abstract

Selon l'invention, on mesure le temps de reponse d'un client sur un reseau et on selectionne une adresse de destination sur la base du temps

de reponse mesure. Le client execute une demande d'adresse au reseau.

Le

reseau peut etre local ou de longue portee tel que l'Internet. Le

temps

de reponse du client est mesure afin de determiner la vitesse

optimale a

laquelle le client peut operer. Le temps de reponse mesure est

communiqué

au serveur sur lequel une adresse de destination est selectionnee en fonction de l'adresse demandee et du temps de reponse mesure. le

client

peut alors etre connecte a l'adresse de destination.

English Abstract

A server broker configured for use in a secure communication network, such as the Internet. The broker is configured to broker client transactions received over a secure network link, such as a secure socket

layer (SSL) link, for distribution among one or more of a plurality

of fulfillment servers. In one embodiment, the broker establishes a non-secure link with the one or more fulfillment servers. In another embodiment, the broker establishes a secure SSL link with the one or more fulfillment servers. The fulfillment server executes client transactions and sends response packets for delivery to the client.

#### French Abstract

L'invention concerne un courtier serveur configure pour s'utiliser dans un reseau de communication securise tel que l'Internet. Le courtier est configure pour envoyer des transactions de clients du courtier recues dans un lien de reseau securise, tel qu'un lien de protocole SSL, a un ou plusieurs serveurs d'execution. Dans un mode de realisation, le courtier etablit un lien non securise avec le ou les serveurs d'execution. Dans un autre mode de realisation, le courtier etablit un lien SSL securise avec le ou les serveurs d'execution. Le serveur d'execution execute les transactions des clients et envoie des paquets reponse a remettre au client.

**English Abstract**

A broker for the management of client requests issued by a client computer over a client-server network. Depending on its availability of resources, the broker determines whether to respond to the client request, or hand-off the client request to another server. The broker supports a virtual connection between the client and the other server, without interfering with communication protocols or disrupting client requests. The other server fulfills client requests by operating in place of the broker. The server terminates the virtual connection when all client requests have been completely fulfilled.

**French Abstract**

L'invention concerne un courtier destine a gerer les demandes client delivrees par un ordinateur client sur un reseau client/serveur. En fonction de sa disponibilite de ressources, le courtier determine s'il peut repondre a la demande client ou s'il doit transférer la demande a un autre serveur. Le courtier supporte alors une connexion virtuelle entre le client et l'autre serveur, sans interferer dans les protocoles de

communication ou interrompre les demandes client. L'autre serveur  
execute  
alors les demandes client en agissant a la place du courtier. Le  
serveur  
termine la connexion virtuelle lorsque toutes les demandes client ont  
ete  
totalement executees.

Abstract: In an error-free system with perfectly clean data, the construction of a global view of the data consists of linking-in relational terms, **joining** -two or more **tables** on their key fields. Unfortunately, most of the time, these data are neither carefully controlled for quality nor necessarily defined commonly across different data sources. As a result, the creation of such a global data view resorts to approximate joins. In this paper, an optimal solution is proposed for the matching or the linking of **database** record pairs in the presence of inconsistencies, errors or missing values in the data. Existing models for record matching rely on decision rules that minimize the probability of error, that is the probability that a sample (a measurement vector) is assigned to the wrong class. In practice though, minimizing the probability of error is not the best criterion to design a decision rule because the misclassifications of different samples may have different consequences. In this paper we present a decision model that minimizes the cost of making a decision. In particular: (a) we present a decision rule: (b) we prove that this rule is optimal with respect to the cost of a decision: and (c) we compute the probabilities of the two types of errors (Type I and Type II) that incur when this rule is applied. We also present a closed form decision model for a certain class of record **comparison** pairs along with an example, and results from **comparing** the proposed cost-based model to the error-based model, for large record **comparison** spaces. Abstract: The choice of **database** layout, i.e., how **database** objects such as tables and indexes are assigned to disk drives can significantly impact the I/O performance of the system. Today, DBAs typically rely on fully striping objects across all available disk drives as the basic mechanism for optimizing I/O performance. While full striping maximizes I/O parallelism, when query execution involves coaccess of two or more large objects, e.g., a merge join of two **tables**, the above strategy may be suboptimal due to the increased number of random I/O accesses on each disk drive. Here, we propose a framework for automating the choice of **database** layout for a given **database** that also takes into account the effects of coaccessed objects in the workload faced by the system. We formulate the above as an optimization problem and present an efficient solution to the problem that judiciously takes into account the trade-off between I/O parallelism and random I/O accesses. Our experiments on Microsoft SQL server show the superior I/O performance of our techniques compared to the traditional approach of fully striping each **database** object across all disk drives. Abstract: The most costly spatial operation in spatial databases is a  
spatial join which combines objects from two data sets based on spatial  
predicates such as intersects or contains. Even if the execution time of  
sequential spatial join processing has improved over the last few years,  
the response time is far from meeting the requirements of interactive  
users. In this paper, we have designed two kinds of parallel spatial join  
algorithms based on grid files: a parallel spatial join using a  
multi-assignment grid file and a parallel spatial join using a  
single-assignment grid file. Three kinds of methods of task allocation for  
improving their performances: static, dynamic, and semi-dynamic, have been  
examined for determining which task allocation strategy based on grid  
files shows the best performance. The experimental tests have been  
conducted on a MIMD parallel machine with shared disks. We conclude that  
the first join algorithm based on disjoint decomposition of data space  
outperforms the second based on non-disjoint decomposition. Also, the  
semi-dynamic task allocation method is the best. (19 Refs)

Abstract: In this paper, we propose a new type of gateway for WWW-Oracle interface, called ORAWIS (ORacle Web Interface System). It supports various types of relational queries on the WWW such as join between two tables, one level nested queries, ORDER BY and GROUP BY operations in a conditional clause. In addition, a application designer can suggest an access method for a table by query selection with a hint option on the WWW. It causes the Oracle optimizer to choose the specified access path. By this function, an application designer can choose more efficient way than the optimizer can determine. The designer can also check the execution time of the SQL statement on the WWW. (8 Refs)

Treatment: Theoretical (T)

Abstract: The paper shows how to combine some well-known techniques to create a method that efficiently executes common multi-table joins. We concentrate on a commonly occurring type of join known as a star-join, although the method presented generalizes to any type of multi-table join. A star-join consists of a central detail table with large cardinality, such as an orders table (where an order row contains a single purchase) with foreign keys that join to descriptive tables, such as customers, products, and (sales) agents. The method uses join indices with compressed bitmap representations, which allow predicates restricting columns of descriptive tables to determine an answer set (or found set) in the central detail table; the method uses different predicates on different descriptive tables in combination to restrict the detail table through compressed bitmap representations of join indices, and easily completes the join of the fully restricted detail table rows back to the descriptive tables. We outline realistic examples where the combination of these techniques yields substantial performance improvements over alternative, more traditional query evaluation plans. (4 Refs)

**Abstract:** Relational **databases** have successfully removed the need for physical navigation. However, they have failed to provide automatic logical navigation, that is, users must specify a logical access path (or join path) when formulating a query. This becomes difficult and error-prone as the size and complexity of a **database** structure increase, especially for the casual user who may not be familiar with the structure of the **database** that he is attempting to query. Also, software applications, including artificial intelligence applications, involving relational **databases** often require some automated means of **determining** join paths in order to properly construct queries. A solution based upon the concept of maximal objects is proposed to provide the automatic logical navigation. The solution consists of two parts: the first part is the design of **database** structures for storing the metadata of the **database** supported by this solution; the second part is the design of a join path generator which utilizes the metadata to provide a join path for an incomplete user query. The user specifies the target tables (relations) in the "FROM" clause of an SQL query, and the join path generator returns the complete "FROM" clause and the additional "WHERE" clause statements necessary in order to properly join the target tables. Language: English Document Type: Journal Paper (JP)

Treatment: Practical (P); Theoretical (T)

**Abstract:** This paper shows how to estimate the size of the natural join of two relations. Such an estimate is valuable in query optimization as joins constitute the bulk of the work required in answering multi-relation queries. The final optimized strategy can be adjusted if an accurate estimate of the size of the resulting joint can be efficiently and reliably **determined**. The estimate is also valuable in distributed systems. Such systems may do an operation called semijoin. A reliable estimate of the size of the final **joined table** gives sufficient information to **determine** whether the semijoin will provide a net gain or net loss in the amount of work required to do the join. The estimation method is based on partial Bloom filters. Bloom filters or segments of filters are prepared from the join attributes of the relations being jointed. It is possible to estimate the size of the **joined table** from the size of the bitwise intersection of the two filters. Estimates of the average number of replications of the join attribute in relation are also available when building the filters. (13 Refs)

Author(s): Lyman, N.

Author Affiliation: Travelers Insurance Co., Hartford, CT, USA

Journal: Info DB vol.7, no.2 p.26-9

Publication Date: Spring 1993 Country of Publication: USA

CODEN: IFDBEB ISSN: 0891-6004

Language: English Document Type: Journal Paper (JP)

Treatment: Practical (P)

Abstract: Another finely tuned query rolls off the assembly line-elapsed time: 7 hours, 8 minutes; CPU time: 5 hours, 20 minutes; rows returned: 32,790,712; DSNDB07 requirements: 6000 cylinders; buffer-pool size: 127 megabytes. These are some of the run-time statistics on one of the author's decision support queries. This query joins six tables whose combined row count exceeds 300 million. These are some of the seventy plus tables which make up a pair of information warehouse applications used for decision support and operational processes at The Travelers Insurance Company in Hartford, Connecticut. The author discusses the high volume tests conducted to determine if DB2 was the correct development platform for these applications. (0 Refs)

Abstract: Multi-Table join is a common operation for evaluating OLAP queries posed to a data warehouse . The performance of this multi-table join is one of the key problems in research of data warehouses . Based on the Star Schema for a data warehouse , this paper introduces a new algorithm M- Join for the multi- table join. Compared with the traditional multi-table join processing by the Relational Database Management System, this new algorithm, taking adequate considerations on the characteristics of the data in a data warehouse environment, completes the join by scanning every table only once, thus greatly improves the performance of OLAP query processing . The paper presents and analyzes the experimental results of this comparison . 8 Refs.

**Abstract:** In this paper, we propose a new direction for distributive join operations. We assume that there will be a scalable distributed computer system in which many computers (processors) are connected through a communication network that can be in a LAN or as part of the Internet with sufficient bandwidth. A relational **database** is then distributed across this network of processors. However, in our approach, the distribution of the **database** is very fine-grained and is based on the Distributed Hash Table (DHT) concept. A tuple of a table is assigned to a specific processor by using a fair hash function applied to its key value. For each joinable attribute, an inverted file list is further generated and distributed again based on the DHT. This pre-distribution is done when the tuple enters the system and therefore does not require any distribution of data tuples on the fly when the join is executed. When a join operation request is broadcast, each processor performs a local join and the results are sent back to a **query processor** which, in turn, merges the join results and returns them to the user. Note that the distribution of the DHT of the inverted file lists can be either preprocessed or distributed on the fly. If the lists are preprocessed and distributed, they have to be maintained. We evaluate our approach by **comparing** it empirically to two other approaches: the naive join method and the fully distributed join method. The results show a significantly higher performance of our method for a wide range of possible parameters.

During the last decade distributed database management systems (DDBMS) have become important information processing systems supporting business activities of geographically decentralized organizations. Since data files are distributed at several locations in a DDBMS, user queries that reference remote files introduce substantial data communication delays. The efficiency of a DDBMS is determined by the speed with which these queries are processed. This dissertation deals with the optimization of query processing in a relational DDBMS. Our objective is to develop a methodological approach to the design of query processing optimizers. The algorithms developed in this dissertation will be valuable tools in the design of a DDBMS.

The first chapter of the dissertation describes a distributed database environment and the importance of query processing in such an environment. The second chapter presents a detailed literature survey. In the third chapter, a special case of queries, star queries, is defined. The requirement for new algorithms to improve system efficiency is demonstrated. Heuristic procedures using greedy approach and a branch and bound solution procedure are proposed. An efficient lower bounding technique is implemented in the branch and bound procedure. The results of extensive computational experiments indicate that the proposed procedures process star queries effectively. Also, the greedy algorithm proves to be insensitive to errors in the selectivity estimation procedures.

The fourth chapter concentrates on the problem of a generalized star query. The problem, an extension of star query, is significantly harder than the star query problem because its optimization model includes an additional operation of joining files. Heuristic and branch and bound solution methods are developed. Extensive computational testing supports the practical feasibility of the solution methods. Also, rigorous analysis of the generalized star query algorithm in a dynamic mode exhibits that the static version is robust to changes in the procedures used to estimate selectivity.

The fifth chapter investigates the use of heuristics in the general query processing problem. Algorithms for the problem of general query processing, which consider various methods of selecting a semijoin in producing a query processing strategy are proposed. Computational experiments are designed to assess the performance of the proposed algorithms relative to existing algorithms. The analyses show that the proposed algorithms outperform the existing algorithms. Chapter six summarizes our work and also discusses future research directions in the field of query processing in DDBMS.

Abstract: The present advances in parallel and distributed processing and its application to **database** operations such as join resulted in investigating parallel algorithms. Hash based join algorithms involve a costly data partitioning phase prior to the join operation. This paper presents new parallel join algorithms for relations based on grid files where no costly partitioning phase is involved, hence the performance can improve. (Author abstract) 10 Refs.

ABSTRACT:

Xprime Inc., in Poway, CA, makes and sells Microsoft SQL servers. The company's president, **Cary Jardin**, a software expert with experience gained at Intel and SCM, uses SolidWorks to design the server faceplates, and then makes rapid prototypes in metal, using a Roland MDX 650 mill with optional rotary axis and VisualMill CAM software. He prefers the Roland DGA mill over plastic-based rapid prototyping (RP) systems because it can work with a broader range of materials. He reports that not only can he prototype his parts in the materials he'll use for the final product, but he can also manufacture small runs directly on the Roland equipment. Michael Jones, an electromechanical technician with Bowe Bell & Howell in Lincolnwood, IL, makes rapid prototypes on a Stratasys fused deposition modeling (FDM) system. The company won an important contract for high-capacity document scanners in large part by redesigning the system and testing design improvements using rapid prototypes. In addition, although designers have changed a part called a flag on the paper carriage several times, the plastic "flag hold-down" made in lots of 100 on the Stratasys system has never worn out, nor has the design been replaced. Michael Huggins, president of Precision CAD/CAM Systems, Hunt Valley, MD, sells equipment and consults for both Stratasys and Roland DGA RP systems. He finds that among his customers, both systems tend to be used at least as much for rapid manufacturing as for RP. "People want to get product off a machine with the fewest possible setups, while they maintain the highest possible quality for usability," he says. "When someone needs a plastic part, they can go from conceptual design to usable part on a Stratasys system-although the parts tend to be small and may need a little finishing. If someone needs to make a precise part in a hurry, the Roland equipment will do the job." Although the systems are very different in nature, some companies use both. They use the Stratasys FDM approach to create a prototype from which a mold may be made-if the surfaces can be made smooth enough. And they use the Roland DGA mill to finish the surfaces for that purpose.

Abstract: Known parallel **DBMS** offer at present only static partitioning schemes. Adding a storage node is a cumbersome operation that typically requires the manual data redistribution. We present an architecture termed **AMOS-SDDS** for a share-nothing multicomputer. We have coupled a high-performance main-memory **DBMS** **AMOS-II** and a manager of Scalable Distributed Data Structures (**SDDS**) into a scalable distributed system **SDDS** provides the scalable data partitioning in distributed RAM, supporting parallel scans with function shipping. **AMOS-SDDS** couples both systems using the **AMOS-II** foreign function interface. Its scalability abolishes the cumbersome storage limits of a single site RAM **DBMS** technology. Its distributed RAM **query processing** and scalable **data** partitioning is an improvement over the current parallel **DBMSs** technology. We validate **AMOS-SDDS** architecture by experiments with distributed nested loop **join** queries over a **file** scaling up to 300,000 tuples. It includes performance study of speed-up and scale-up characteristics. The results encourage the use of **SDDS** for high-performance **database** systems. (19 Refs)

**Abstract:** Commonly used content-retrieval systems focus on the problem of finding the nearest neighbor (NN-search) for a given single query object out of a **database** of media objects. However, there are only few attempts that realize join operations on two multimedia tables, where the multimedia data components are represented by their respective feature vectors. The necessity of using multimedia joins in a variety of applications is the motivation behind this search for a more efficient and more general purpose method of performing a **join** on multimedia **tables**. In this perspective, the goal of this paper is to introduce an efficient implementation of such a multimedia join using the method of NN-search. The problem is naturally related to the NN-search for a single query object which suggests a straightforward nested-loop implementation. We show that this implementation can be considerably improved by extending the notion of a query object to a query-sphere. Finally we demonstrate experimentally that our implementation decreases considerably the number of index partitions to be accessed. (12 Refs)

Treatment: Theoretical (T)

Abstract: How to process user-defined functions incorporated in declarative query languages efficiently is an important aspect of query optimization. The problem of several user-defined functions in a query clause has not solved in the previous researches. In this paper, a 3-stage optimization plan is put forward which has the potency of processing several user-defined functions in a query clause: 1) rewrite user-defined functions equivalently in the form of interval constraints; 2) stratify the constraints and eliminate the redundant once; and 3) select the optimal execution strategy. This plan has the virtue of easy implementation and higher efficiency. Especially, when the user-defined functions imply join conditions of several tables, this plan can lead an optimization result. **Abstract:** Although First American National Bank initially licensed Platinum Technology's InfoReports query tool, I found I needed functionality that exceeded that product's capabilities. InfoReports is supposed to make the query job easy; and, for simple queries involving one or two tables, it did. However, I quickly found that this tool was not suitable for the complex queries we often required. To monitor the retention, acquisition, and defection of customers, for example, we wanted to measure not only the added or lost households, but also all the added or lost accounts that were associated with those households. (In the automated householding process, accounts may sometimes be split between households or regrouped into new households for arbitrary reasons, such as a change of address form sent in for one but not all associated accounts. This splitting, of course, is not a real indication that we have acquired or lost a customer.) This kind of query requires a derived table. Queryman and Teradata handle derived tables nicely, but InfoReports does not. I also found that InfoReports produced very slow and inefficient SQL code when we needed, for example, outer **joins**. Subqueries, derived **tables**, and temporary tables were similarly difficult or impossible to execute. To meet these advanced user needs, the bank installed Queryman on all Teradata users' PCs. Abstract: Scalability and resource usage are hot topics of discussion in the ever-changing world of n-tier programming. Network round-trips and expensive **database** queries can reduce application performance severely and even cause applications to fail. Such fundamental **database** programming issues confront most developers at some point in their careers, and knowing the most efficient way to approach the issues is essential. I show how to use master/detail **database** relationships to deal effectively with the problem of **joining** two **database** **tables** to present information. You will need ActiveX Data Objects and Visual Basic 6.0. (0 Refs)

Abstract: In maintaining **data warehouse** views without interfering current **databases**, a **join differential file** (JDF) scheme is introduced. The scheme uses differential files from relevant logs of **databases** and **join differential files** by capturing the referential integrity signal between the base relations. Cost functions are formulated, that analyze the performance of the JDF, the base method, and the pseudo differential method in various conditions. The algorithm is shown to be much better than the other two methods with high communication speed, more screening and small **join differential files**. (17 Refs)

Abstract: A novel indexing structure-the join index hierarchy-is proposed to handle the "gotos on disk" problem in object-oriented **query processing** . The method constructs a hierarchy of join indices and transforms a sequence of pointer-chasing operations into a simple search in an appropriate **join index file** , and thus accelerates navigation in object-oriented **databases** . The method extends the join index structure studied in relational and spatial **databases** , supports both forward and backward navigation among objects and classes, and localizes update propagations in the hierarchy. Our performance study shows that a partial join index hierarchy outperforms several other indexing mechanisms in object-oriented **query processing** . (34 Refs)

Abstract: WHIRL is an extension of relational **databases** that can perform "soft joins" based on the similarity of textual identifiers; these soft joins extend the traditional operation of **joining tables** based on the equivalence of atomic values. This paper evaluates WHIRL on a number of inductive classification tasks using data from the World Wide Web. We show that although WHIRL is designed for more general similarity-based reasoning tasks, it is competitive with mature inductive classification systems on these classification tasks. In particular, WHIRL generally achieves lower generalization error than C4.5, RIPPER, and several nearest-neighbor methods. WHIRL is also fast-up to 500 times faster than C4.5 on some benchmark problems. We also show that WHIRL can be efficiently used to select from a large pool of unlabeled items those that can be classified correctly with high confidence. (11 Refs)

**Abstract:** Since multi-dimensional arrays are a natural data structure for supporting multi-dimensional queries, and object-relational (O/R) **database** systems support multi-dimensional array ADTs (abstract data types), it is natural to ask if a multi-dimensional array-based ADT can be used to improve O/R **DBMS** performance on multi-dimensional queries. As an initial step toward answering this question, we have implemented a multi-dimensional array in the Paradise O/R **DBMS**. In this paper, we describe the implementation of this compressed-array ADT and explore its performance for queries including star-join consolidations and selections. We show that, in many cases, the array ADT can provide significantly higher performance than can be obtained by applying techniques such as bitmap indices and star-join algorithms to relational **tables**. Abstract: This paper describes a universal technique for data retrieval from a **database** file afflicted with repeating groups. The procedure relies on a generic "repeater" table which is **joined** to the unnormalized **table**. Though the physical data model may violate first normal form, the proposed technique produces a data view that overcomes that violation. The importance of this technique to the design and use of **databases** is demonstrated through an actual case study. (5 Refs)

Abstract: At the North Temperate Lakes Long-Term Ecological Research site, our centralized relational **database** is accessible from the Internet. Initially we used Gopher to serve up flat files of data extracted from **database** tables to Internet users. These files must be maintained separately as the central **database** is updated. Such files cannot be queried or linked to provide a subset, summary or **join** of **data files**. Search and display capabilities are quite limited. We then investigated low-cost methods to access our **database** directly and dynamically via the World-Wide Web (WWW). The freeware Perl5 library called Dbperl was tested to provide HTML CGI access to our Oracle 7 **database**. The PGLOT.pm and CGI.pm Perl5 modules were also essential. We contrast flat file access with the Perl5 interface we developed. Now our Dbperl development enables WWW users to do interactive queries on the fly and provides the current version of the data. Abstract: In traditional relational **databases**, the **data** are stored in 'flat' tables. **Query processing** performance is dominated by the cost of **joining** such **tables**. By contrast, nested relational structures can avoid joints. If, however, such structures are decomposed into nested normal form (NNF) then the number of normal scheme trees in the resulting nested scheme forest may dominate **query processing** performance. Thus, minimizing the number of such trees is an important design goal. We prove that the problem of finding a succinct NNF scheme forest is NP-hard even for the class of sets of unary multivalued dependencies, which is a subclass of the class of split-free sets of multivalued dependencies. Abstract: Since relational **database** management systems typically support only diadic join operators as primitive operations, a query optimizer must choose the 'best' sequence of two-way joins to achieve the N-way **join** of **tables** requested by a **query**. The computational complexity of this optimization **process** is dominated by the number of such possible sequences that must be evaluated by the optimizer. This paper describes and measures the performance of the Starbust join enumerator, which can parametrically adjust for each query the space of join sequences that are evaluated by the optimizer to allow or disallow: composite tables (i.e., tables that are themselves the result of a join) as the inner operand of a join; and **joins** between two **tables** having no joint predicate linking them (i.e., Cartesian products). **Abstract:** The time required to execute batch transactions is becoming longer because of the increasing size of **databases** and because batch transaction queries are becoming more complex. Batch transactions include range queries executed with and without the use of indexes, **join** queries and **table** merge operations which include index updating. Execution time can be reduced by introducing intra-parallelism in the processing of these transactions. The authors propose a load balancing algorithm and an index structure on a shared memory multiprocessor system to achieve highly scalable intra-parallelism in executing batch transactions. In the proposed algorithm, the number of allocated tasks is dynamically calculated on the basis of the number of remaining tasks and the max/min processing time of each task to decrease the overhead of parallel execution. The proposed index structure is a hybrid structure consisting of some B-trees associated with a hashing function. Highly parallel execution of range queries and table merges requiring index operations is achieved with this hybrid structure. The effects of the adaptive load balancing and hybrid index structure are evaluated by a prototype **DBMS** implemented in a shared memory multiprocessor. The performance evaluation shows the adaptive algorithm can increase the scalability by 0.1 to 0.2. Range queries and table merging requiring index operations can be easily executed in parallel by using the hybrid index structure. (16 Refs)

Abstract: A design methodology for a distributed **database** query simulator (DDQS) is discussed. A distributed **database** query consists of two different types of sub tasks; the tasks pertaining to the relational **database** manipulation language, such as project and **joins** on different **files** ; and the tasks of file transfers. A given query can have any number of subtasks of both types. These tasks are interrelated, and parallel operations can be performed provided the required serialization is maintained. The subtasks compete for common resources; with subtasks from other queries being evaluated at the same time, or, to some degree, with the subtasks from the same query if performed in parallel. The purpose of the DDQS is to evaluate the performance of a given **query** algorithm in terms of the total **query processing** time, in a given workload and network architecture. The DDQS uses transaction-oriented GPSS language to simulate the query, while Pascal is used to generate the GPSS source code relevant to the query. The DDQS design is highly modular and simulation of any communication protocol layers or **database** access methods can be changed without affecting the higher level modules. (7 Refs)

The new and substantially upgraded version of the Table File System in MIDAS is presented as a scientific **database** system. MIDAS applications for performing **database** operations on tables are discussed, for instance, the exchange of the data to and from the TFS, the selection of objects, the uncertainty **joins** across **tables**, and the graphical representation of data. This upgraded version of the TFS is a full implementation of the binary table extension of the FITS format; in addition, it also supports arrays of strings. Different storage strategies for optimal access of very large data sets are implemented and are addressed in detail. As a simple relational **database**, the TFS may be used for the management of personal **data files**. This opens the way to intelligent pipeline **processing** of large amounts of **data**. One of the key features of the Table File System is to provide also an extensive set of tools for the analysis of the final results of a reduction process. Column operations using standard and special mathematical functions as well as statistical distributions can be carried out; commands for linear regression and model fitting using nonlinear least square methods and user-defined functions are available. Finally, statistical tests of hypothesis and multivariate methods can also operate on tables.

Abstract: Star schema is often used in dimensional approaches applied to OLAP applications. The fact table in the star schema typically contains a huge amount of data. When some of the dimension tables are also very large, it may take too much time and storage to **join** the fact **table** with these dimension tables. The performance of join algorithm becomes critical under such a condition. The fluent join is a join algorithm that operates on relations organized as multidimensional linear hash files. Like a merge join on relations which are already sorted on the joining key, its execution reads each page in the operand relations no more than once and does not create intermediate result files. Unlike sorting, the multidimensional linear has can cluster records in several keys symmetrically. In this paper, the concept of the fluent join is applied to an OLAP system to cluster records in each table on the joining keys. As a result, the algorithm yields symmetric performances on **joins** with different dimension **tables** . (Author abstract) 18 Refs.

Abstract: A novel indexing structure - join index hierarchy - is proposed to handle the 'gotos on disk' problem in object-oriented **query processing**. The method constructs a hierarchy of join indices and transforms a sequence of pointer chasing operations into a simple search in an appropriate **join index file**, and thus accelerates navigation in object-oriented **databases**. The method extends the join index structure studied in relational and spatial **databases**, supports both forward and backward navigations among objects and classes, and localizes update propagations in the hierarchy. Our performance study shows that partial join index hierarchy outperforms several other indexing mechanisms in object-oriented **query processing**. (Author abstract) 34 Refs.

Journal Announcement: 9411W3

**Abstract:** In 1989, Tandem introduced intra-query parallelism to NonStop SQL. Table scans and aggregates as well as nested-loop and merge joins could be performed in parallel. Near-linear speedup and scaleup were demonstrated for straightforward scans, aggregates and nested loop joins. Scalability is an inherent objective of these environments, since query times should remain relatively constant regardless of the size of the large tables. To improve the scalability of typical decision support queries, Tandem has added parallel implementations of hash joins, cross product joins and hashed groupings to Non Stop SQL. Hash joins are useful when a large table is joined with a smaller one, especially if there are no useful indexes on the join columns. we briefly describe the hash join algorithm and use results from a customer benchmark to illustrate why it is often superior to merge joins and nested-loop joins under the given circumstances. Cross products (or 'star joins ') allow small tables to be joined without predicates if there is a subsequent equijoin of the composite table to another table. They can reduce the need to scan large tables in joins. Results from the customer benchmark demonstrate their usefulness. We also describe hashed groupings, which eliminate sorts to form groups for subsequent aggregation. Hashed groupings allow execution of queries in the benchmark that were previously impossible.

Journal Announcement: 8906

Abstract: Using the NJOY nuclear **data processing** system, three multigroup MATXS-formatted nuclear **data** libraries were generated based on the European **data files** JEF-1 and EFF-1. After **processing** with TRAMIX, TRANSX, or TRANSX-CTR, these libraries can be read into most transport and diffusion codes. For the neutron analysis of gas-cooled or water moderated thermal reactor systems (including high converter pressurized water reactors), a 70-group WIMS-BOXER structured library was generated. A general-purpose fine-group library in 308 groups is provided for thermal as well as for fast reactor systems. A coupled 175 neutron/42 photon-group library in VITAMIN-J structure was created for the analysis of shielding problems and fusion blanket design. The three MATRXS files can be requested from the Nuclear Energy Agency **Data Bank**. (Author abstract)

**Mining decentralized data repositories**

Author: Jensen, Viviane Crestana

Degree: Ph.D.

Year: 2001

Corporate Source/Institution: University of Michigan (0127)

Chair: Nandit Soparkar

Source: VOLUME 62/08-B OF DISSERTATION ABSTRACTS INTERNATIONAL.

PAGE 3688. 134 PAGES

ISBN: 0-493-35826-9

Technology for data mining, i.e., finding useful trends and patterns in large **data repositories**, has acquired significant importance with increasing availability of online data. While such technology is typically applied to centrally stored data, real-life **database** design and management, and performance aspects suggest the mining of decentralized data, which consists of several tables, perhaps obtained via normalization or partitioning and allocation, stored in several repositories with possibly separate administration and schema. The few prior extensions to mining for such **data** have algorithms developed largely for parallel **processing** as opposed to addressing the specific issues for decentralized data. Most approaches to mining decentralized data require the separate tables to be joined to form a single table.

In contrast, this dissertation presents techniques for mining decentralized data that do not require the **join** of all **tables**. The approach exploits foreign key relationships to develop decentralized algorithms that execute concurrently on the separate tables, and thereafter merge the results. We develop our techniques using the specific example of association rules discovery. Important issues concerning the merging of partial results, the computation and memory requirements, and the associated costs and trade-offs are examined.

Several different decentralized strategies arise, and an algebra is presented which allows enumeration of the many different decentralized mining strategies, each with different processing costs. Based on this algebra, heuristics are developed that reduce the overall computation, I/O, and communication costs. When cost estimates are available for the basic operations, there is an opportunity to optimize for the best strategy in a manner similar to **query processing**. As such, our approach may be suitably integrated with available **query processing** algorithms for large-scale decentralized **data** mining.

Our decentralized approach is empirically validated, and in cases of interest it performs significantly better than the typical centralized approach. Several decentralized alternatives are implemented, and the heuristic rules are validated, i.e., are shown to choose optimal or nearly optimal plans. The decentralized approach presented in this dissertation may be adapted to different counting strategies, different storage structures, incremental mining, and to exploit indices and summary data where available; some of these improvements are infeasible in a centralized approach.

This dissertation provides an approach to decentralized mining that establishes its feasibility and importance, and opens numerous new avenues for research in data mining.

#### Alerting Abstract US B1

NOVELTY - An input vertical stack processor has record transitioning routine for transitioning previous version of record into current version for use in creating application input file, and allows individual records to grow horizontally by using reserved unused space and vertically by adding records without requiring all existing users to make synchronized changes. An application processor processes the application input file.

DESCRIPTION - INDEPENDENT CLAIMS are also included for the following:

- 1.destination data file production system; and
- 2.data file processing method.

USE - Used for processing data file such as financial data file in financial institution such as bank.

ADVANTAGE - Enables to implement changes in the record with minimum affect on the users.

DESCRIPTION OF DRAWINGS - The figure shows the block diagram of the data processing service provider.

12 data processing service provider

**Alerting Abstract US A1**

NOVELTY - The method involves comparing a portion of one database  
table with two join tables. Another portion of the table is  
compared with the two join tables to generate two intermediate results  
files. A final results file is generated from the two intermediate  
results files. The portions of the two database tables on a node  
are stored in equal portions. Post-processing operations are executed on  
the final results file.

DESCRIPTION - An INDEPENDENT CLAIM is included for a distributed database  
system for processing a database query command in which database  
tables are stored on nodes, different portions of database table  
stored on two of the nodes.

USE - Used for processing a query command in a distributed computing  
system (claimed) e.g. distributed database system and distributed task  
system.

ADVANTAGE - The method provides a superior performance of high-speed  
distributed computing system in a clustered environment. The method makes  
the distributed computing system to return processing results to a  
requestor in significantly reduced times.

DESCRIPTION OF DRAWINGS - The drawing shows a block diagram of a database  
system.

- 100 Database system
- 110 Client
- 120 Network
- 130 Database server
- 140 Storage

**Technology Focus**

INDUSTRIAL STANDARDS - The node is connected to a secondary node via an  
inter-nodal communication link conforming to the -IEEE 1596- standards.

#### Alerting Abstract US A1

NOVELTY - An initial correlation order specifying sequence for accessing one or more tables, is established between two database in response to a requested query. The correlation order is selected, if its cost strategy is favorable.

USE - For determining optimal correlation order in relation database system e.g SQL database system.

ADVANTAGE - Since the correlation order is selected based on the cost strategy, optimal correlation order is determined and complex queries are optimized efficiently.

DESCRIPTION OF DRAWINGS - The figure shows the block diagram of the computer system.

#### Alerting Abstract US B1

**NOVELTY** - A variation design is created by applying variation assignment to group of logic functions, which specifies one of style, logic option, clique assignment, position and timing requirements, family, device, speed grade and global default parameter that are not provided in the assignment data of a base design. Using a GUI, the base and variation designs are selected for compilation, and the compiled design is output to respective files.

**DESCRIPTION** - INDEPENDENT CLAIMS are also included for the following:

1. Electronic design designing apparatus;
2. Design tool;
3. Computer readable medium storing data structure used in computer for electronic circuit designing

**USE** - For creating and refining electronic design for multiple electronic circuits e.g. multichip module and integrated circuits, programmable logic circuits such as programmable logic arrays and programmable gate arrays, etc.

**ADVANTAGE** - Provides simple mechanism by allowing designer to efficiently create, maintain and **compare** multiple variations of the design. Provides convenient user interface and associated variation control system. Eliminates the need to create separate programs or scripts that parse through and modify existing design files in an effort to create and compile variation design.

**DESCRIPTION OF DRAWINGS** - The figure shows the block diagram of the associated data file that includes both base design and variation changes of the associated data.

#### Alerting Abstract US B1

NOVELTY - The method involves performing Boolean operations using bitmap entries of star maps to produce bitmap entries in a star map, where there is a corresponding set bitmap entry in one of the former maps and no corresponding set bitmap entry in the other former map. The latter map is used to **identify** qualifying rows from a table. The **identified** qualifying rows are provided as an exclusion join result.

DESCRIPTION - INDEPENDENT CLAIMS are also included for the following:

- 1.a computer program, stored on a tangible storage medium, for performing an exclusion join of two tables
- 2.a database system for accessing a database , comprising a massively parallel processing system.

USE - Used for performing exclusion join of two tables , in a database system (claimed) that is utilized in e.g. personal computer, mainframe and minicomputer.

ADVANTAGE - The utilization of the star maps improves the performance of exclusion joins that have low join cardinality.

DESCRIPTION OF DRAWINGS - The drawing shows an illustration of a hardware and software environment that is used with **tables exclusion join** performing method.

- 104 Network
- 108 Data communications units
- 112 Parallel data extensions

#### Alerting Abstract US B1

NOVELTY - A join index having record identifiers corresponding to the tables stored in the database, is received. The join index is sorted according to one of the record identifiers and is resorted according to another record identifier. The join operation is performed between the spatial join attributes using the resorted portion of the join index.

DESCRIPTION - INDEPENDENT CLAIMS are also included for the following:

- 1.data sorting system; and
- 2.article comprising medium storing data sorting program;
- 3.computer-implemented method of updating join index; and
- 4.article comprising medium storing join index updating program.

USE - For sorting data in parallel object-relational database management system (ORDBMS).

ADVANTAGE - The join indices provides efficient access to auxiliary relations during joining operations. Hence, the parallel spatial join operations are performed effectively, in the database system.

DESCRIPTION OF DRAWINGS - The figure shows the flowchart explaining the parallel spatial join operation.

#### **Alerting Abstract WO A1**

The **database** join method involves reading a portion of a join index and the first input table's records **identified** by the read join index into a relatively fast memory. The first table's records are sorted by the second tables index entry in the read join index. The read records from the first input table are written to separate first output files and the second sorted table's index entries are written to second files. These steps are repeated until all portions of the join index are read.

The second output files are merged to a lowest second index table entry which has not been previously **identified** during the join. A record is read from the second input table corresponding to the lowest index entry. The record is placed in an appropriate output buffer. The previous two steps are repeated until all the join index **identifiers** are processed.

**ADVANTAGE** - Provides efficient **joining** of multiple large **tables** in **database** system using processor with small **main** memory.

**Title Terms/Index Terms/Additional Words:** FIRST; SECOND; INPUT; TABLE; JOIN ; **DATABASE** ; SYSTEM; RECORD; FAST; MEMORY; SORT; INDEX; OUTPUT; FILE; WRITING

#### Alerting Abstract GB A

The system joins distributed data with a join key and produces a joined table (100,200). Recording devices, disk drives (4a-4d) store the distributed data e.g. employee data (5a-5d) and sales data (6a-6d). Slave-processors (3a-3d) are coupled to the recording devices to retrieve the data and output the data. The main processor (1) receives the data from the slave-processors and produces the joined table.

Each slave-processor **checks** a join key of the second data, sales data, with a join key of the first data. Based on the **checking** result it selects the second data (400a-400d) and outputs the data to the main processor.

USE/ADVANTAGE - Provides high speed joining, eliminates burden on master processor as data distributed and stored in slave processors, part of join processing done in parallel.

#### **Alerting Abstract EP A**

The method for **joining** selected data in **two tables** (12,10) in a relational data base system which involves defining a **first parameter** (35), selecting data in the first table which satisfies the first parameter and placing such selected data in order in a first sub-table (38). A second parameter is defined and data is selected in the second table which satisfies the second parameter.

Selecting data which satisfies the second parameter involves defining a preliminary parameter based on the data in the first sub-table. Data in the second table is selected which satisfies the preliminary parameter and placed in order in a second sub table (45). Data in the second sub table which satisfies the second parameter is selected and combined with the data in the first sub table so as to **join** the selected data in the first and second tables (50).

ADVANTAGE - Highly efficient I/O operations. @(14pp Dwg.No.5/5)@

#### **Equivalent Alerting Abstract US A**

The machine-executed method for **joining two relational database tables** involves **comparing** the rows of the first table with a local predicate and retrieving rows of the first table which satisfy the local predicate and entering the rows into a sort table. The rows of the sort table are ordered by joining column values and retrieving, from the index, **identifiers** of rows of the second table having **join** column values satisfying a join predicate and entering the **identifiers** in a row index (RID) list.

Rows matching the **identifiers** are retrieved. The rows of the sort table are **compared** with a local predicate and combined with the rows retrieved to produce composite rows satisfying the local predicate and entering the composite rows in an intermediate result table.

USE/ADVANTAGE - Database management. Safe joining technique. Highly

efficient I/O.

#### Alerting Abstract US A1

NOVELTY - Each query block is identified within the received query specifying **join** conditions between **database tables**. The subplans are created based on grouping portions of query blocks. The favorable access plans are **determined** for subplans based on estimated execution costs. The optimal access plan is generated for each query block based on favorable access plans for constructing the optimal query execution plan.

DESCRIPTION - INDEPENDENT CLAIMS are also included for the following:

- 1.method for generating bushy trees during optimization of database query;
- 2.method for optimizing executing of query.

USE - For constructing optimal query execution plan in **database** management system ( **DBMS** ) which is version 8.0 of **\*\*sybase adaptive server anywhere\*\*** (ASA) implemented in international business machine (IBM) - compatible personal computer (PC) or server computer, and for use in workgroup, mobile and embedded applications.

ADVANTAGE - Requires minimal memory as only the information about the best access plan are stored.

DESCRIPTION OF DRAWINGS - The figure shows the block diagram of the client/server **database** system.

- 330 server
- 361 parser
- 363 normalizer
- 365 compiler
- 369 execution unit

**Alerting Abstract US A1**

NOVELTY - A predefined data structure and tables are stored. The skipping of partial group-by operation, is **determined** in response to data elements in the data structure.

DESCRIPTION - INDEPENDENT CLAIMS are also included for the following:

1. article comprising computer- readable medium storing tables joining program; and
2. database system.

USE - For joining tables in **database** system (claimed) using structured query language (SQL).

ADVANTAGE - Enhances efficiency by skipping partial group operations in response to certain predefined conditions. Reduces number of rows of base tables and intermediate spools, by performing partial group-by operations, thereby reducing processing required to perform join query plan.

DESCRIPTION OF DRAWINGS - The figure shows the block diagram of database system.

#### Alerting Abstract US B1

NOVELTY - A hybrid hash join process joins data rows from two tables that have common data column by partitioning the data rows based on the values in the common data columns. The tables are defined as outer and inner dependent on size.

DESCRIPTION - The smaller outer table's hit rows are partitioned into outer partitions based on common column data. The outer hit row is stored in an outer buffer logically linked to the assigned outer partition. The outer hit rows are joined with inner hit rows from the partitioned inner table, based on column data, so there is a one-to-one correspondence between the outer and inner partitions. The inner hit row is stored in an inner buffer. The outer partition is searched when the inner buffer is full by allocating each outer hit row to a data entry based on the value of the common column of the outer hit row. The data structure is searched for a matching outer hit row for each inner hit row in the full inner buffer. Any matching hit rows are outputted.

INDEPENDENT CLAIMS are made for:

1.A computer program for joining data rows from two tables that have common column data.

2.A hybrid hash join process for joining data rows from two tables.

USE - Hash joining process searches in relational database systems.

ADVANTAGE - Data structures decrease the data search time for matching rows and recovering from full data buffers by using other buffer space.

**Alerting Abstract US A**

NOVELTY - The query for generating the tuple stream satisfying the selection criteria is executed, by scanning the selected database tables (250) according to the determined join order. The inner most table is scanned, thereby executing the filter which filters the duplicate tuples from the tuple stream.

DESCRIPTION - A received query specifies the selection criteria for the information of interest from the database system. The determined join order indicates the innermost and outermost tables of the selected join so as to guarantee that the tuples will stream in order during scanning of the query. A filter is initialized at the outermost table for key columns to pass the initial tuple encountered from which an initial key is constructed. On execution the tuples having keys already encountered in the tuple stream are discarded by the filter attached to the innermost table.

USE - For eliminating duplicate tuples in a generated tuple stream in a database management system.

ADVANTAGE - The duplicate tuples are eliminated from the tuple stream without the need for performing an expensive sort operation by the described method.

DESCRIPTION OF DRAWINGS - The figure is a block diagram of a client-server system with the duplicate tuples elimination method.

#### Alerting Abstract US A

The **database** access system includes one or more applications having a logical data access interface for requesting data access according to a logical data model. The data model has numerous interrelated logical entity types each with numerous logical attributes. A **RDBMS** contains numerous physical tables derived from the logical data model, each having numerous columns. A logical to physical data mapping table maps each logical entity type and logical attribute pair to a physical table name and a physical column name as stored in the **RDBMS**.

A **join table** has a **join** entry for each logical entity type represented by more than one physical table in the **RDBMS**. Each **join** entry identifies the physical tables and columns to join, and the join criteria necessary to form the logical entity type represented by the join entry. A logical data access module receives a logical **database** request from a requesting application via it's logical data interface. One or more **database** queries having physical table and physical column names are formed using the logical to physical data mapping and **join** criteria tables.

**ADVANTAGE** - Allows change in physical structure of **database** tables without changing client applications. Allows DBA to tune **database** without changing client applications. Application can update views without knowing physical table names used in constructing view. Permits re-engineering **database** for maximum performance without modifying applications. Provides logical views without knowing join criteria.

#### Alerting Abstract EP A

Data is retrieved using a request including a set of joint statements, each linking the name of two tables. The data processor includes an element to assign priority to one table name in each joint statement. An array of graph identifiers corresponding to the table names is formed. Each group identifier is initialised to have a value representing the corresponding table name. Each joint statement is processed in succession.

The value of the priority name is substituted in the array of graph identifier values in place of each value representing the other name to derive an indication of the number of groups of linked names in the set of entered join statements.

USE/ADVANTAGE - Assures coherency of join list without need for re-entering all of elements of join list.

#### Equivalent Alerting Abstract US A

An interactive prompted query system is implemented in a database system having a number of named database tables which a user can link together for query purposes by entering join statements. The join statements are analyzed by determining that one or more groups of separately linked database table names are referenced in the join statements. If more than one group exists, then the join statements are adjusted so that only a single group of separately linked database table names is referenced by the join statements.

The single group of names may be determined by selecting the group which contains the name first entered by the user, by selecting the group

which contains the highest number of names, by prompting the user to select the group or by any other logical means. More particularly, the join statements are analyzed using a graphical technique to **determine** the groups of tables. The tables are represented as nodes and the join relationships are represented as lines. The lines are traced to **determine** all of the nodes connected to form a single graph. Each graph represents a separately linked group of **database** tables.

ADVANTAGE - Assures list coherency, without re-entering all join list elements.

#### Alerting Abstract US A1

NOVELTY - A specific query comprising identified leaf nodes of a join tree is optimized, and the exclusive parents of the leaf nodes are examined. The nodes in which merging opportunities exist, are selectively

merged. The combined factors for the merged nodes are calculated, to **determine** the order of execution of the nodes.

DESCRIPTION - An INDEPENDENT CLAIM is also included for computer program

product for performing structured query language optimization method.

USE - For performing optimization of structured query language (SQL) in computer system.

ADVANTAGE - Enables improving the efficiency of the computer system, by

optimizing the structured query language using simple process.

DESCRIPTION OF DRAWINGS - The figure shows the flowchart explaining the structured **query** language optimization **process** .

#### Alerting Abstract US A1

NOVELTY - The system has a **database** administrator (14) that receives application programs through an open **data base** connectivity interface. The administrator maintains a checkpoint file (22) and a journal file (24).

A structured **query** language (SQL) **processing** integrated circuit (IC)

(44A, 44B) processes industry standard SQL commands. A content addressable memory (46A, 46B) stores the processed commands.

USE - Used for managing structured query language **database** for Internet business.

ADVANTAGE - The integrated circuit processes the industry standard structured query language commands, thereby increasing the memory bandwidth. The integrated circuit distributes the data load across the buses, thereby increasing the memory densities while decreasing the cost.

DESCRIPTION OF DRAWINGS - The drawing shows a data flow diagram of an integrated circuit based structured query language **database** management system.

Title Terms.../Index Terms/Additional Words: DATABASE ;

**Original Publication Data by Authority**

**Original Abstracts:**

A distributed SQL database management system includes an SQL-processing integrated circuit capable of processing industry standard SQL commands...

...at a high abstraction level. The use of the SQL integrated circuit and distributed SQL database management system significantly increases memory bandwidth. The SQL integrated circuit performs the following SQL functions:

**table joins** , view support, learning mode extension, proximity match extension, longest prefix match extension, SQL DML support...

**Claims:**

Having thus described the invention, what is claimed is:    b 1 /b . A distributed SQL **database** management system comprising at least one dedicated SQL-processing integrated circuit.

#### Alerting Abstract US A1

NOVELTY - The method involves **determining a join sequence to join tables** from a query in a primary pass by creating a set of mini-plans simulating all possible joins of a predetermined subset of the query tables and using cost model calculations. The **determined join sequence is then** used in a secondary pass to create an access path for **processing the query** .

DESCRIPTION - An INDEPENDENT CLAIM is also included for a computer based processor system for **determining optimum join sequence for processing a query** .

USE - Used for processing a multi-table structured query language (SQL) query in a relational **database** stored in electronic devices.

ADVANTAGE - The **determination** of the detailed access path in secondary pass by using the optimum join sequence **determined** in the primary pass eliminates the expensive EXPLAIN tables and avoids storage usage expense problem.

DESCRIPTION OF DRAWINGS - The drawing shows a computer hardware and software environment that enables a two-pass dynamic programming algorithm in join sequence **determining** method.

NOVELTY - An inverter list of keywords that maps the data record components to a region of **database** containing corresponding data record,  
is created. The regions of **database** containing data records relating to  
the given search keyword, are identified by accessing the inverted list. A

query is constructed corresponding to the given search criteria and is executed on the identified regions of **database** .

DESCRIPTION - INDEPENDENT CLAIMS are also included for the following:

1. computer readable medium storing instructions to perform data record

search process ; and

2. data records search apparatus.

USE - For searching data records in **database** comprising address information of employee, mailing list information, product and sales details.

ADVANTAGE - The records matching the search criteria are efficiently retrieved by executing the query on the identified regions. The keyword searching on relational **database** is made efficient.

DESCRIPTION OF DRAWINGS - The figure shows the flowchart of data record search process .

Alerting Abstract WO A1

NOVELTY - Apparatus has a program store for parsing the **data processing** statement, identifying the referenced table field or fields, **determining** whether the field is a looked-up field, identifying the basis table, identifying target tables and generating an SQL statement (Select, Insert, Update, Delete) plus fields selected from a basis table and From clause. If the statement contains fields to be looked up, Outer or Inner Join and On clauses are included for the target table rows, the conditions being look-up fields.

USE - Apparatus is for relational **database** tables.

ADVANTAGE - Apparatus requires less processing skill.

DESCRIPTION OF DRAWINGS - The figure shows operation of an SQL generator.

Query processing method for database management system, involves  
rewriting query that does not reference particular materialized view,  
only

when particular materialized view satisfies predetermined conditions

Patent Assignee: ORACLE CORP (ORAC-N)

Inventor: BELLO R; FINNERTY J; WITKOWSKI A; ZIAUDDIN M

Patent Family (1 patents, 1 countries)

Patent			Application			Update
Number	Kind	Date	Number	Kind	Date

#### Alerting Abstract US B1

NOVELTY - A query that does not reference a particular materialized  
view  
and requires access to values from a particular column not contained in  
the

materialized view, is received. The query is rewritten only when the  
particular materialized view satisfies predetermined conditions, to  
produce

a rewritten query that references the materialized view, and joins the  
view

back to a join-back table that contains the particular column.

DESCRIPTION - An INDEPENDENT CLAIM is included for computer readable  
medium storing query processing program.

USE - For processing queries in database management system (  
DEMS  
).

ADVANTAGE - Since only the materialized views satisfying  
predetermined  
conditions are used for processing the queries, query execution  
speed

is improved and size of the database containing the materialized  
views is  
reduced. Hence, overhead associated with maintaining the materialized  
views

that are not necessary is eliminated.

DESCRIPTION OF DRAWINGS - The figure shows a flowchart illustrating  
the  
query execution process.

#### Patent Details

Number	Kind	Lan	Pg	Dwg	Filing	Notes
US 6421657	B1	EN	9	4		

#### Alerting Abstract US B1

NOVELTY - The cost of building using initial set of composites are **determined** . The cost of building for next successive larger set of composites whose value does not exceed the threshold value are calculated.

The **determination** unit **determines** whether the final composite is used

for calculating the cost of the building based on which the lowest value of

the building is saved.

DESCRIPTION - INDEPENDENT CLAIMS are included for the following:

- 1.Method for calculating threshold value of a composite;
- 2.Computer readable medium storing threshold value calculation program;
- 3.Lowest cost permutation determination system;
- 4.Computer readable medium storing lowest cost permutation determination program; and
- 5.System for calculating threshold value.

USE - For **database** management system for use with **data processor**

ADVANTAGE - The lowest cost permutation is **determined** efficiently minimizing the computation time. Also the CPU storage and elapse time are significantly reduced.

DESCRIPTION OF DRAWINGS - The figure shows the flowchart explaining

the  
method of calculating threshold value.

#### Alerting Abstract US A1

NOVELTY - A database tables join order is determined in  
response

to a received database query which specifies a predetermined join  
condition that should exist between an inner table and an outer table.

Rows

of successive tables are retrieved in the join order to test whether  
the  
rows satisfy the join condition. The join condition satisfied rows are  
included in the query.

USE - Database query processing method for database  
management  
system for decision support and OLAP used for client/server  
applications.

ADVANTAGE - Enables optimizing nested loop joins more efficiently, by  
ordering tables according to prescribed join condition.

DESCRIPTION OF DRAWINGS - The figure shows the block diagram of a  
computer software system.

#### Patent Details

Number	Kind	Lan	Pg	Dwg	Filing	Notes
US 6185557	B1	EN	13	4		

#### Alerting Abstract US B1

NOVELTY - When performing equijoin operations on two tables, as long as

outer **table join** column value is less than or equal to last key value,

the same data page from inner table will be searched repeatedly.

Therefore

inner table index records will not be revisited until outer **table join**

column is greater than last data page key value. Combination of next key

and last key allows merge join process to **determine** that entire ranges of

outer rows do not have matching inner rows.

DESCRIPTION - INDEPENDENT CLAIMS are also included for the following:

1.A computer readable medium having computer executable modules for joining data rows from two tables .

2.A merge join process for joining data rows from two tables which

have a common data column.

USE - Relational **database** systems

ADVANTAGE - Designed to minimize processor time and file input and output

when performing equijoin operations on two tables. Reduces or eliminates

searches of the inner index records and the data pages. Reduces cache thrashing on the inner index records and so the required index record is

likely to be in the cache when needed. Minimizing the traversal of the index records and data pages on mass storage minimizes the number of

operations performed, and therefore provides a more efficient search process. Also , because the merge join process is structurally suited for execution on the multi-processor computers, the speed of the **database** queries can be increased through parallel processing.

#### Alerting Abstract EP A1

NOVELTY - A processor (3) **determines** whether the input requires a link of data in different tables and whether aggregation is needed. If required, the **processor** generates a **query** causing the **database** (2) to aggregate the data from the required tables.

DESCRIPTION - An INDEPENDENT CLAIM is also included for **data base** system.

USE - For generating a query for obtaining selected data from and into the **database**.

ADVANTAGE - The query generator can efficiently handle the calculation of aggregation and linking of data that are stored in different tables. Complex folder structure construction is eliminated when handling a mis-interpreted data.

DESCRIPTION OF DRAWINGS - The figure shows an example of **database** system incorporating a **query** generator and **processor**.

#### Alerting Abstract EP A1

NOVELTY - The rules which are recorded are those flowing from the  
application of each decision criteria in a decision tree model. The  
decisions will typically involve yes/no multiple choice questions and  
data

are applied to the decision criteria one at a time, in hierarchical  
order.

Each application provides a rule which is recorded to make all the  
decisions easily explicable.

DESCRIPTION - INDEPENDENT CLAIMS are included for

1.apparatus for providing a description of logic used in processing  
data

2.and a program storage device readable by a computer and embodying  
instructions to cause the computer to perform a method of providing

a

description of logic used in processing data.

USE - Managing databases.

ADVANTAGE - Provides a comprehensible description of an automated data

processing function, e.g. to comply with legislation entitling individuals

to an explanation of the outcome produced by an automated data processing system.

#### Alerting Abstract US A

NOVELTY - If materialized view reflecting specific set of aggregate functions satisfies each set condition, the query is rewritten to produce a rewritten query that references the view. The results of particular function for target population, is derived from variance, sum and count of source population.

DESCRIPTION - The query specifies a predetermined set of aggregate functions including particular function to be applied to target population. The target applied function is an aggregation function comprising variance and standard deviation. The set of conditions include that each aggregate function in predetermined set should be computable from corresponding functions in specific set. The argument to each function in predetermined set should be equivalent to that of corresponding functions in specific set. During testing of each function in predetermined set, it is **determined** whether the particular materialized view includes variance, sum and count of source population on which target population is functionally dependent. An INDEPENDENT CLAIM is also included for a computer program product.

USE - For **database management system**.

ADVANTAGE - The number of materialized views that a **database** must contain to efficient process particular set of queries, is reduced, thus reducing size of **database** and eliminating overhead associated with maintaining the materialized view. Allows more number of queries to correspond with set of materialized views thus improving execution speed.

DESCRIPTION OF DRAWINGS - The figure shows the steps involved in

aggregate compatibility test.

**Alerting Abstract US A**

NOVELTY - The tuples of two **tables** are **joined** by union of a left outer join with a right outer join lesser than matched tuples from right

outer join, using a full outer join. The join condition is free from restrictions of type of join conditions specified.

DESCRIPTION - A **data processor** stores **data** in the form of two tables each defining an operand, which is retrievable by query language.

The join condition is selected from the set of **comparison** operators like

IS NULL, LIKE, EQUALS, DOES NOT EQUAL, IS GREATER THAN, IS LESS THAN, IS

GREATER THAN OR EQUAL TO, IS LESSER THAN OR EQUAL TO. The **comparison** operators are combined with logical operators such as AND, OR, and NOT. An

INDEPENDENT CLAIM is also included for a full outer join specification apparatus.

USE - For relational **database** management system.

ADVANTAGE - The method enables the use of a modified merge join to implement full outer join which enables the use of arbitrary join conditions other than the equality predicate. A full outer join is implemented with any join condition without any new runtime operators.

DESCRIPTION OF DRAWINGS - The figure shows flow chart of implementing full outer join with any join condition.

#### Alerting Abstract US A

NOVELTY - During composition predicates listing each data value to be accessed from remote table and range of values are provided. During run time if count of data values in local **table** to be **joined** with values in remote table exceeds threshold value, the predicate indicating range of values is assigned in a query to a **DEMS** and data access is carried out.

DESCRIPTION - If the count does not exceed threshold value then predicate indicating list of each data value is assigned to a **DEMS** through a structured query language. During predicate assigning, utilization of collating sequences by **DEMS** is also **determined**. An INDEPENDENT CLAIM is also included for memory media for controlling table linking operation.

USE - For linking **database** table using structured query languages for application program interface.

ADVANTAGE - Communication cost is reduced by avoiding fetch of unnecessary rows from outer table. Performance of merge operation is improved by reducing cardinality of outer table.

DESCRIPTION OF DRAWINGS - The figure shows logical flow diagram which illustrates operational method of table linking.

#### Alerting Abstract EP A2

The query system includes a query engine with the capability to build objects in a memory based on a view type referenced in a query received from an application. Query rewrite optimisations are applied to the query

referencing the view type to minimise the number of objects built for the

query. Objects are built if the query requests a handle.

Some of the predicates of the query are pushed down to the **database** management system to restrict the results and in this way restrict the number of objects that have to be built to resolve the query.

USE - For systems, methods, and programs in field of integrating object

technology with **database** technology in client server environment.

ADVANTAGE - Minimises number of objects built for query.

#### Alerting Abstract EP A2

The computer implemented method (2) selects a join order for a query having two or more join operations and computes a value of a Sigma metric

for each join order of a set of possible join orders. A join order is selected for the query using the computed values of the Sigma metric.

The value of the join order of is the sum of cardinalities over all the joins in the join order. An estimate of the cardinality of each join is generated as it is performed in the join order; the cardinality of a

join

is the number of tuples that will result from the join.

USE - Query optimisation in **database** system and to join order optimisation in relational **database** systems.

ADVANTAGE - Calculates good join order in multiple join order query by using metric designed to **compare** relative efficiencies of alternative join orders.

#### **Alerting Abstract US A**

The query optimisation method involves examining the WHERE clause and finding all join conditions that are present. A chain of the join conditions is formed.

A list of tables is established where i) tables that are in the WHERE clause but not in the join conditions are listed first; ii) **tables** in the

**join** chains formed according to graph theory are listed next in the same

order as they appear in the join chain such that the tables from the longest chains are listed before the tables from shorter chains and all tables at a given distance from a root table of the chain occur together

before the next level in the **join** chain. The **tables** are reordered in

the FROM clause in the list order.

ADVANTAGE - Quickly finds access plan. Orders tables in FROM clause according to optimal join order in WHERE clause **determined** by graph theory.

#### Alerting Abstract EP A2

The method involves processing a query of the database, the query

containing query tables. Weights for each pair of query tables are **determined**, the weights is indicative of occurrence of the query table pairs in previous queries. Sets of the query table pairs are **determined**

based on the weights. One of the sets which contains query tables specified in the query are sent to the computer output device. A grouping threshold level is based upon display size of the computer output device so that each the set of the sending step can be substantially displayed within display size of the computer output device. One of the query tables is selected for a focused display on the computer output device, the focused display is provided for displaying all attributes of the selected query table and all attributes of neighbours of the selected query table on the computer output device.

ADVANTAGE - Allows user to make use of very small display surface such as those found in mobile computer such as personal digital assistant.

#### Alerting Abstract US A

The system includes a central processing unit with a first memory storage device containing at least a first normalised, relational **database**. A second memory device coupled to the central processing unit, has a push-pop stack area and a storage area for nodes.

The first memory device has a set of instructions for controlling the central processing unit to parse the outer join protocol statement into a number of tokens for execution by the central processing unit in accord with the grammar, syntax and semantics, of ANSI-92 SQL2 outer join protocol for controlling the actions of the central processing unit. The tokens from the outer join statement are sequentially parsed to identify if the token being parsed is a **table** name, **join** type (left or right), or a join condition.

ADVANTAGE - Increases accuracy and efficiency of cental processing units operation.

#### Alerting Abstract CA A

The relational **database** management method involves **determining** whether tables referenced in a query include a hub table (T0) and at least two encoding tables or spoke tables (T1-T4). This involves counting the number of tables which are joined to each **table** in memory by **join** predicates and storing the identity of the table with the largest number of tables joined to it.

When a hub table is identified a best access plan is constructed for joining the hub table and associated spoke tables. A plan for joining all tables reference in the query statement is generated. All of the plans are enumerated to **determine** the best plan for joining the tables reference in the query statement.

USE/ADVANTAGE - Optimises queries in relational **databases** which reference encoding/decoding tables.

**Title Terms/Index Terms/Additional Words:** RELATED; **DATABASE** ; OPTIMUM; METHOD; ENCODE; DECODE; TABLE; IDENTIFY; HUB; GENERATE; ACCESS; PLAN;

#### Alerting Abstract US A

The method involves establishing a user query as to a set of tables. followed by reducing the user query into component joins in the form of f(A) join f(B), or constant join f(A), wherein f(A) represents a function

upon the fields of a table A and f(B) represents a function upon the fields

of a table B.

The method also entails establishing a processing order for the tables,

which is selected so as to be consistent with that required by any outer-joins in the user query, e.g. the first in order table comprises the

root. Further it includes evaluating each component join to produce respective pointer table indexes.

USE/ADVANTAGE - In computerised relational **data base** . Speed up qualification **processing** of **data base** that eliminates needs for user defined index.

#### Alerting Abstract EP A2

The system has a device for storing tables consisting of a number of  
tuples having multiple columns. An outer join operation is performed on  
two

such tables, one table being an inner table and the other an outer. The  
outer table is ordered or indexed in a sorted sequence on a selected  
set of  
columns.

A device, responsive to values in the selected set of columns,  
**determine**

a number of responsibility regions in the inner table such that every  
tuple in the inner table belongs to one and only one region. The tuples  
of

the inner table are processed in each responsibility region by  
outputting  
all tuples which belong to the region.

ADVANTAGE - Is capable of outputting all tuples of inner **table** in output of **join** operation without requiring sorting of inner table.

**Title Terms/Index Terms/Additional Words:** DATA; PROCESS; SYSTEM; EXECUTE;

Inventor name & address:

**Jardin, Cary Anthony ...**

**Original Abstracts:**

The present invention provides a system for distributing **database**  
processing across a loosely coupled hardware platform, or a computer  
cluster. The system divides the data held within the **database** across  
all  
available resources, and then submits the **database** queries in  
parallel to  
all points of data storage. Once all resources have received and  
processed  
the **database** query, the results are sent back to a single point for  
final  
reassembly.

**Claims:**

What is claimed is: b 1 /b . A method for distributed **database**  
processing in a clustered computing environment comprising: a) a  
computer

cluster defined as a group...

...ability to programmatically communicate with one another via  
electrical

or optical connection; and b) a **database** server on each computer in  
the  
cluster.

#### Alerting Abstract US A1

NOVELTY - The method involves determining whether a database  
request  
received by a master database system is an information retrieval  
request  
or storage request. The request is determined to be a local or remote  
request. The master database behavior is invoked to retrieve the  
requested information if the request is a local request. The request is  
forwarded to a remote slave system for retrieval if the request is a  
remote  
request.

USE - Used for accelerating database performance in a business.

ADVANTAGE - The method allows the existing database applications to  
delegate costly transactions to the main memory database system while  
maintaining persistent and coherent storage on the existing database,  
thereby providing increased information retrieval speed.

DESCRIPTION OF DRAWINGS - DESCRIPTION OF DRAWING - The drawing shows  
a  
block diagram of a database request handling system to accomplish  
database acceleration.

Jardin, Cary Anthony ...

**Original Abstracts:**

The present invention provides a system to allow existing database applications to delegate costly transactions to a main memory database system while maintaining persistent and coherent storage on the existing database. The system utilizes database heterogeneous transaction support to delegate desired transaction without modification of existing database application logic. Persistency is maintained on the host database by replicating state change operations onto the associated main memory system.

In this way, the present invention provides the performance of a main memory database system, with the required persistency of existing database technologies.

**Claims:**

What is claimed is: b 1 /b . A method for cooperative database performance comprising:a) database system with heterogeneous query support (master); andb) main memory database system (slave).

#### Alerting Abstract US A1

NOVELTY - A network packet having database transaction, is  
selectively intercepted. The database transaction is translated to a desired  
vendor-specific form, and the source and destination addresses of a  
newly created packet are selectively masked, based on the nature of the  
database

transaction.

DESCRIPTION - INDEPENDENT CLAIMS are included for the following:

1. database translating system; and
2. database transactions translating system.

USE - For translating database transactions to desired vendor  
specific form in electronic commerce and real-time information retrieval  
applications.

ADVANTAGE - Enables translating and analyzing the database  
transactions, effectively. The newly created packet is transparent to  
other devices in the network, as the source and destination addresses of the  
newly created packet are selectively masked.

DESCRIPTION OF DRAWINGS - The figure shows a flow chart explaining  
the database transactions translation process.

#### Alerting Abstract US A1

NOVELTY - The method involves determining whether there is a  
database  
transaction in a network packet. The packet is cut off if the result is  
positive and then its kind is also determined. A database  
acceleration  
technique is selectively put into practice based on above  
determination.

Another network packet is formed with one of its source and destination  
address being selectively masked based on nature of the transaction.

DESCRIPTION - An INDEPENDENT CLAIM is also included for system for  
improving network database performance.

USE - Used for network-based database acceleration.

ADVANTAGE - The method improves the database acceleration and

increased

**database** performance that is transparent to **database** applications.  
The

method is thus compatible with various **database** application software  
as

well as existing general-purpose and server hardware.

DESCRIPTION OF DRAWINGS - The drawing shows a flow chart  
representation  
of a method for accelerating **database** transactions associated with  
packets intercepted from a client machine.

**Title Terms/Index Terms/Additional Words:** **DATABASE ; TRANSACTION;**

**TECHNIQUE; FORM**

**Class Codes**

International Classification (Main): G06F-012/00, G06F-015/16  
(Additional/Secondary): G06F-015/04

File Segment: EPI;

DWPI Class: T01; W01

Manual Codes (EPI/S-X): T01-J05B3; T01-J05B4P; T01-N02A1; W01-A03B;  
W01-A06E; W01-A06G2

Database transactions accelerating method, involves determination of  
database transaction and its kind in one network packet and  
application of  
database acceleration technique to form another network packet

**Original Titles:**

**Alerting Abstract** ...NOVELTY - The method involves determining  
whether  
there is a **database** transaction in a network packet. The packet is  
cut  
off if the result is positive and then its kind is also determined. A  
**database** acceleration technique is selectively put into practice based  
on  
above determination. Another network packet is...  
DESCRIPTION - An INDEPENDENT CLAIM is also included for system for  
improving network **database** performance...

...USE - Used for network-based **database** acceleration...

...ADVANTAGE - The method improves the **database** acceleration and  
increased **database** performance that is transparent to **database**

applications. The method is thus compatible with various **database** application software as well as existing general-purpose and server hardware...

...DESCRIPTION OF DRAWINGS - The drawing shows a flow chart representation of a method for accelerating **database** transactions associated with packets intercepted from a client machine.

Title Terms/Index Terms/Additional Words: **DATABASE** ;

Original Publication Data by Authority

Inventor name & address:

JARDIN C ...

... Jardin, Cary A ...

... JARDIN, Cary

Original Abstracts:

A method and system for accomplishing transparent network **database** acceleration. The architecture determines from the nature of a packet on a network the whether the packet is a **database** transaction. If the packet is a **database** transaction, it is suitably intercepted for further analysis. **Database** acceleration techniques are then suitably implemented based on the type of **database** transaction. A new packet is then created such that it appears to the devices on...

...A method of improving network **database** performance is disclosed (Fig. 1). The method comprises steps of determining whether a first network packet involves a **database** transaction (14) and then intercepting the packet upon a positive determination. The packet is then examined to determine the nature of the **database** transaction (18). Depending on the nature of the **database** transaction, a **database** acceleration technique is selectively implemented (22...

Claims:

What is claimed is: b 1 /b . A method of improving network **database** performance comprising the steps of: a) determining whether a first network packet involves a **database** transaction; b) intercepting the first network packet upon a positive determination in step a); c) determining the nature of the **database** transaction; d) selectively implementing a **database** acceleration technique based upon the determination in step c); e) creating a second network packet...

### 1 [Fast detection of communication patterns in distributed executions](#)

Thomas Kunz, Michiel F. H. Seuren

 November 1997 **Proceedings of the 1997 conference of the Centre for Advanced Studies on Collaborative research**

Publisher: IBM Press

Full text available: pdf(4.21 MB)

 Additional Information: [full citation](#), [abstract](#), [references](#), [index terms](#)

Understanding distributed applications is a tedious and difficult task. Visualizations based on process-time diagrams are often used to obtain a better understanding of the execution of the application. The visualization tool we use is Poet, an event tracer developed at the University of Waterloo. However, these diagrams are often very complex and do not provide the user with the desired overview of the application. In our experience, such tools display repeated occurrences of non-trivial commun ...

### 2 [Link and channel measurement: A simple mechanism for capturing and replaying wireless channels](#)

Glenn Judd, Peter Steenkiste

 August 2005 **Proceeding of the 2005 ACM SIGCOMM workshop on Experimental approaches to wireless network design and analysis E-WIND '05**

Publisher: ACM Press

Full text available: pdf(6.06 MB)

 Additional Information: [full citation](#), [abstract](#), [references](#), [index terms](#)

Physical layer wireless network emulation has the potential to be a powerful experimental tool. An important challenge in physical emulation, and traditional simulation, is to accurately model the wireless channel. In this paper we examine the possibility of using on-card signal strength measurements to capture wireless channel traces. A key advantage of this approach is the simplicity and ubiquity with which these measurements can be obtained since virtually all wireless devices provide the req ...

**Keywords:** channel capture, emulation, wireless

### 3 [GPGPU: general purpose computation on graphics hardware](#)

David Luebke, Mark Harris, Jens Krüger, Tim Purcell, Naga Govindaraju, Ian Buck, Cliff Woolley, Aaron Lefohn

 August 2004 **Proceedings of the conference on SIGGRAPH 2004 course notes SIGGRAPH '04**

**Publisher:** ACM PressFull text available:  [pdf\(63.03 MB\)](#) Additional Information: [full citation](#), [abstract](#)

The graphics processor (GPU) on today's commodity video cards has evolved into an extremely powerful and flexible processor. The latest graphics architectures provide tremendous memory bandwidth and computational horsepower, with fully programmable vertex and pixel processing units that support vector operations up to full IEEE floating point precision. High level languages have emerged for graphics hardware, making this computational power accessible. Architecturally, GPUs are highly parallel s ...

**4** Collision detection and proximity queries

Sunil Hadap, Dave Eberle, Pascal Volino, Ming C. Lin, Stephane Redon, Christer Ericson  
August 2004 **Proceedings of the conference on SIGGRAPH 2004 course notes**  
**SIGGRAPH '04**

**Publisher:** ACM PressFull text available:  [pdf\(11.22 MB\)](#) Additional Information: [full citation](#), [abstract](#)

This course will primarily cover widely accepted and proved methodologies in collision detection. In addition more advanced or recent topics such as continuous collision detection, ADFs, and using graphics hardware will be introduced. When appropriate the methods discussed will be tied to familiar applications such as rigid body and cloth simulation, and will be compared. The course is a good overview for those developing applications in physically based modeling, VR, haptics, and robotics.

**5** Human-computer interface development: concepts and systems for its management

H. Rex Hartson, Deborah Hix  
March 1989 **ACM Computing Surveys (CSUR)**, Volume 21 Issue 1

**Publisher:** ACM PressFull text available:  [pdf\(7.97 MB\)](#) Additional Information: [full citation](#), [abstract](#), [references](#), [citations](#), [index terms](#), [review](#)

*Human-computer interface management*, from a computer science viewpoint, focuses on the process of developing quality human-computer interfaces, including their representation, design, implementation, execution, evaluation, and maintenance. This survey presents important concepts of interface management: dialogue independence, structural modeling, representation, interactive tools, rapid prototyping, development methodologies, and control structures. *Dialogue independence* is th ...

**6** Level set and PDE methods for computer graphics

David Breen, Ron Fedkiw, Ken Museth, Stanley Osher, Guillermo Sapiro, Ross Whitaker  
August 2004 **Proceedings of the conference on SIGGRAPH 2004 course notes**  
**SIGGRAPH '04**

**Publisher:** ACM PressFull text available:  [pdf\(17.07 MB\)](#) Additional Information: [full citation](#), [abstract](#), [citations](#)

Level set methods, an important class of partial differential equation (PDE) methods, define dynamic surfaces implicitly as the level set (iso-surface) of a sampled, evolving nD function. The course begins with preparatory material that introduces the concept of using partial differential equations to solve problems in computer graphics, geometric modeling and computer vision. This will include the structure and behavior of several different types of differential equations, e.g. the level set eq ...

**7** The elements of nature: interactive and realistic techniques

Oliver Deussen, David S. Ebert, Ron Fedkiw, F. Kenton Musgrave, Przemyslaw Prusinkiewicz, Doug Roble, Jos Stam, Jerry Tessendorf  
August 2004 **Proceedings of the conference on SIGGRAPH 2004 course notes**  
**SIGGRAPH '04**

**Publisher:** ACM PressFull text available:  [pdf\(17.65 MB\)](#) Additional Information: [full citation](#), [abstract](#)

This updated course on simulating natural phenomena will cover the latest research and production techniques for simulating most of the elements of nature. The presenters will provide movie production, interactive simulation, and research perspectives on the difficult task of photorealistic modeling, rendering, and animation of natural phenomena. The course offers a nice balance of the latest interactive graphics hardware-based simulation techniques and the latest physics-based simulation techni ...

## 8 Industrial sessions: beyond relational tables: Garlic: a new flavor of federated query processing for DB2

Vanja Josifovski, Peter Schwarz, Laura Haas, Eileen Lin

June 2002 **Proceedings of the 2002 ACM SIGMOD international conference on Management of data SIGMOD '02****Publisher:** ACM PressFull text available:  [pdf\(1.05 MB\)](#) Additional Information: [full citation](#), [abstract](#), [references](#), [citations](#), [index terms](#)

In a large modern enterprise, information is almost inevitably distributed among several database management systems. Despite considerable attention from the research community, relatively few commercial systems have attempted to address this issue. This paper describes new technology that enables clients of IBM's DB2 Universal Database to access the data and specialized computational capabilities of a wide range of non-relational data sources. This technology, based on the Garlic prototype deve ...

## 9 Parallelism in relational data base systems: architectural issues and design approaches

Hamid Pirahesh, C. Mohan, Josephine Cheng, T. S. Liu, Pat Selinger

July 1990 **Proceedings of the second international symposium on Databases in parallel and distributed systems****Publisher:** ACM PressFull text available:  [pdf\(2.50 MB\)](#) Additional Information: [full citation](#), [abstract](#), [references](#), [citations](#), [index terms](#)

With current systems, some important complex queries may take days to complete because of: (1) the volume of data to be processed, (2) limited aggregate resources. Introducing parallelism addresses the first problem. Cheaper, but powerful computing resources solve the second problem. According to a survey by Brodie,<sup>1</sup> only 10% of computerized data is in data bases. This is an argument for both more variety and volume of data to be moved into data base systems. We conject ...

## 10 A Survey of Some Theoretical Aspects of Multiprocessing

J. L. Baer

March 1973 **ACM Computing Surveys (CSUR)**, Volume 5 Issue 1**Publisher:** ACM PressFull text available:  [pdf\(4.05 MB\)](#) Additional Information: [full citation](#), [references](#), [citations](#), [index terms](#)

## 11 Speeding up construction of PMR quadtree-based spatial indexes

Gisli R. Hjaltason, Hanan Samet

October 2002 **The VLDB Journal — The International Journal on Very Large Data Bases**, Volume 11 Issue 2**Publisher:** Springer-Verlag New York, Inc.Full text available:  [pdf\(355.72 KB\)](#) Additional Information: [full citation](#), [abstract](#), [citations](#), [index terms](#)

Spatial indexes, such as those based on the quadtree, are important in spatial databases for efficient execution of queries involving spatial constraints, especially when the queries involve spatial joins. In this paper we present a number of techniques for speeding up the construction of quadtree-based spatial indexes, specifically the PMR quadtree, which can index arbitrary spatial data. We assume a quadtree implementation using the "linear quadtree", a disk-resident representation ...

**Keywords:** Bulk-loading, I/O, Spatial indexing

## 12 Pen computing: a technology overview and a vision

André Meyer

July 1995 **ACM SIGCHI Bulletin**, Volume 27 Issue 3

**Publisher:** ACM Press

Full text available: [pdf\(5.14 MB\)](#) Additional Information: [full citation](#), [abstract](#), [citations](#), [index terms](#)

This work gives an overview of a new technology that is attracting growing interest in public as well as in the computer industry itself. The visible difference from other technologies is in the use of a pen or pencil as the primary means of interaction between a user and a machine, picking up the familiar pen and paper interface metaphor. From this follows a set of consequences that will be analyzed and put into context with other emerging technologies and visions. Starting with a short historic ...

## 13 Abstraction-based intrusion detection in distributed environments

Peng Ning, Sushil Jajodia, Xiaoyang Sean Wang

November 2001 **ACM Transactions on Information and System Security (TISSEC)**,  
Volume 4 Issue 4

**Publisher:** ACM Press

Full text available: [pdf\(590.61 KB\)](#) Additional Information: [full citation](#), [abstract](#), [references](#), [citations](#), [index terms](#), [review](#)

Abstraction is an important issue in intrusion detection, since it not only hides the difference between heterogeneous systems, but also allows generic intrusion-detection models. However, abstraction is an error-prone process and is not well supported in current intrusion-detection systems (IDSs). This article presents a hierarchical model to support attack specification and event abstraction in distributed intrusion detection. The model involves three concepts: *system view*, *signature* ...

**Keywords:** Cooperative information systems, heterogeneous systems, intrusion detection, misuse detection

## 14 Real-time shading

Marc Olano, Kurt Akeley, John C. Hart, Wolfgang Heidrich, Michael McCool, Jason L. Mitchell, Randi Rost

August 2004 **Proceedings of the conference on SIGGRAPH 2004 course notes SIGGRAPH '04**

**Publisher:** ACM Press

Full text available: [pdf\(7.39 MB\)](#) Additional Information: [full citation](#), [abstract](#)

Real-time procedural shading was once seen as a distant dream. When the first version of this course was offered four years ago, real-time shading was possible, but only with one-of-a-kind hardware or by combining the effects of tens to hundreds of rendering passes. Today, almost every new computer comes with graphics hardware capable of interactively executing shaders of thousands to tens of thousands of instructions. This course has been redesigned to address today's real-time shading capabilities ...

15 A robust protocol for parallel join operation in distributed data bases

S. Bandyopadhyay, A. Sengupta

January 2000 **Proceedings of the first international symposium on Databases in parallel and distributed systems**

**Publisher:** IEEE Computer Society Press

Full text available:  [pdf\(1.23 MB\)](#)

Additional Information: [full citation](#), [abstract](#), [references](#), [citations](#), [index terms](#)

Fault tolerant distributed databases use replicated data(e.g., record or relation) to handle failures of one or more nodes in a computer network. Efficient and economic access strategies for such data bases have not been investigated. In this paper, the binary hypercube, a popular model for fault tolerant interconnection networks, has been studied. It has been shown that, for a local area network based on a binary hypercube, having 2<sup>n</sup> nodes where every data is replicate ...

16 Technical reports

SIGACT News Staff

January 1980 **ACM SIGACT News**, Volume 12 Issue 1

**Publisher:** ACM Press

Full text available:  [pdf\(5.28 MB\)](#)

Additional Information: [full citation](#)

17 Real-time volume graphics

Klaus Engel, Markus Hadwiger, Joe M. Kniss, Aaron E. Lefohn, Christof Rezk Salama, Daniel Weiskopf

August 2004 **Proceedings of the conference on SIGGRAPH 2004 course notes SIGGRAPH '04**

**Publisher:** ACM Press

Full text available:  [pdf\(7.63 MB\)](#)

Additional Information: [full citation](#), [abstract](#)

The tremendous evolution of programmable graphics hardware has made high-quality real-time volume graphics a reality. In addition to the traditional application of rendering volume data in scientific visualization, the interest in applying these techniques for real-time rendering of atmospheric phenomena and participating media such as fire, smoke, and clouds is growing rapidly. This course covers both applications in scientific visualization, e.g., medical volume data, and real-time rendering, ...

18 Scaling up the semantic web: On labeling schemes for the semantic web

Vassilis Christophides, Dimitris Plexousakis, Michel Scholl, Sotirios Tourounis

May 2003 **Proceedings of the 12th international conference on World Wide Web**

**Publisher:** ACM Press

Full text available:  [pdf\(294.32 KB\)](#)

Additional Information: [full citation](#), [abstract](#), [references](#), [citations](#), [index terms](#)

This paper focuses on the optimization of the navigation through voluminous subsumption hierarchies of topics employed by Portal Catalogs like Netscape Open Directory (ODP). We advocate for the use of labeling schemes for modeling these hierarchies in order to efficiently answer queries such as subsumption check, descendants, ancestors or nearest common ancestor, which usually require costly transitive closure computations. We first give a qualitative comparison of three main families of schemes ...

19 Extensions to Starburst: objects, types, functions, and rules

Guy M. Lohman, Bruce Lindsay, Hamid Pirahesh, K. Bernhard Schiefer

### 1 [Research sessions: query processing I: A scalable hash ripple join algorithm](#)

Gang Luo, Curt J. Ellmann, Peter J. Haas, Jeffrey F. Naughton

 June 2002 **Proceedings of the 2002 ACM SIGMOD international conference on Management of data SIGMOD '02**

Publisher: ACM Press

Full text available: [pdf\(1.12 MB\)](#)
 Additional Information: [full citation](#), [abstract](#), [references](#), [citations](#), [index terms](#)

Recently, Haas and Hellerstein proposed the hash ripple join algorithm in the context of online aggregation. Although the algorithm rapidly gives a good estimate for many join-aggregate problem instances, the convergence can be slow if the number of tuples that satisfy the join predicate is small or if there are many groups in the output. Furthermore, if memory overflows (for example, because the user allows the algorithm to run to completion for an exact answer), the algorithm degenerates to bl ...

### 2 [Improving lookup latency in distributed hash table systems using random sampling](#)

Hui Zhang, Ashish Goel, Ramesh Govindan

 October 2005 **IEEE/ACM Transactions on Networking (TON)**, Volume 13 Issue 5

Publisher: IEEE Press

Full text available: [pdf\(511.97 KB\)](#)
 Additional Information: [full citation](#), [abstract](#), [references](#), [index terms](#)

Distributed hash table (DHT) systems are an important class of peer-to-peer routing infrastructures. They enable scalable wide-area storage and retrieval of information, and will support the rapid development of a wide variety of Internet-scale applications ranging from naming systems and file systems to application-layer multicast. DHT systems essentially build an overlay network, but a path on the overlay between any two nodes can be significantly different from the unicast path between those ...

### 3 [Low traffic overlay networks with large routing tables](#)

Chunqiang Tang, Melissa J. Buco, Rong N. Chang, Sandhya Dwarkadas, Laura Z. Luan, Edward So, Christopher Ward

 June 2005 **ACM SIGMETRICS Performance Evaluation Review , Proceedings of the 2005 ACM SIGMETRICS international conference on Measurement and modeling of computer systems SIGMETRICS '05**, Volume 33 Issue 1

**Publisher:** ACM Press

Full text available:  [pdf\(269.80 KB\)](#) Additional Information: [full citation](#), [abstract](#), [references](#), [index terms](#)

The routing tables of Distributed Hash Tables (DHTs) can vary from size  $O(1)$  to  $O(n)$ . Currently, what is lacking is an analytic framework to suggest the optimal routing table size for a given workload. This paper (1) compares DHTs with  $O(1)$  to  $O(n)$  routing tables and identifies some good design points; and (2) proposes protocols to realize the potential of those good design points. We use total traffic as the uniform metric to compare heterogeneous DHTs a ...

**Keywords:** distributed hash table, overlay network, peer-to-peer system

#### 4 Avoiding Cartesian products for multiple joins

Shinichi Morishita

January 1997 **Journal of the ACM (JACM)**, Volume 44 Issue 1

**Publisher:** ACM Press

Full text available:  [pdf\(583.81 KB\)](#) Additional Information: [full citation](#), [abstract](#), [references](#), [index terms](#), [review](#)

Computing the natural join of a set of relations is an important operation in relational database systems. The ordering of joins determines to a large extent the computation time of the join. Since the number of possible orderings could be very large, query optimizers first reduce the search space by using various heuristics and then try to select an optimal ordering of joins. Avoiding Cartesian products is a common heuristic for reducing the search space, but it cannot guarantee optimal or ...

**Keywords:** Cartesian product, database scheme, join expression tree, join strategy, optimality, semijoin

#### 5 Incrementally improving lookup latency in distributed hash table systems

Hui Zhang, Ashish Goel, Ramesh Govindan

June 2003 **ACM SIGMETRICS Performance Evaluation Review , Proceedings of the 2003 ACM SIGMETRICS international conference on Measurement and modeling of computer systems SIGMETRICS '03**, Volume 31 Issue 1

#### 6 Research sessions: spatial data: Joining interval data in relational databases

Jost Enderle, Matthias Hampel, Thomas Seidl

June 2004 **Proceedings of the 2004 ACM SIGMOD international conference on Management of data**

**Publisher:** ACM Press

Full text available:  [pdf\(552.80 KB\)](#) Additional Information: [full citation](#), [abstract](#), [references](#)

The increasing use of temporal and spatial data in present-day relational systems

necessitates an efficient support of joins on interval-valued attributes. Standard join algorithms do not support those data types adequately, whereas special approaches for interval joins usually require an augmentation of the internal access methods which is not supported by existing relational systems. To overcome these problems we introduce new join algorithms for interval data. Based on the Relational Interval ...

## 7 Efficient processing of spatial joins using R-trees

Thomas Brinkhoff, Hans-Peter Kriegel, Bernhard Seeger

June 1993 **ACM SIGMOD Record , Proceedings of the 1993 ACM SIGMOD international conference on Management of data SIGMOD '93**, Volume 22 Issue 2

**Publisher:** ACM Press

Full text available: pdf(1.48 MB)

Additional Information: [full citation](#), [abstract](#), [references](#), [citations](#), [index terms](#)

Spatial joins are one of the most important operations for combining spatial objects of several relations. The efficient processing of a spatial join is extremely important since its execution time is superlinear in the number of spatial objects of the participating relations, and this number of objects may be very high. In this paper, we present a first detailed study of spatial join processing using R-trees, particularly R\*-trees. R-trees are very suitable for supporting spatial queries a ...

## 8 Failure recovery for structured P2P networks: protocol design and performance evaluation

Simon S. Lam, Huaiyu Liu

June 2004 **ACM SIGMETRICS Performance Evaluation Review , Proceedings of the joint international conference on Measurement and modeling of computer systems SIGMETRICS '04/Performance '04**, Volume 32 Issue 1

**Publisher:** ACM Press

Full text available: pdf(481.82 KB)

Additional Information: [full citation](#), [abstract](#), [references](#), [index terms](#)

Measurement studies indicate a high rate of node dynamics in p2p systems. In this paper, we address the question of how high a rate of node dynamics can be supported by *structured* p2p networks. We confine our study to the hypercube routing scheme used by several structured p2p systems. To improve system robustness and facilitate failure recovery, we introduce the property of *K-consistency*,  $K \geq 1$ , which generalizes consistency defined previously. (Consistency guarantees ...

**Keywords:** failure recovery, hypercube routing, k-consistency, peer-to-peer networks, sustainable churn rate

## 9 Research session: query optimization and summarization: REED: robust, efficient filtering and event detection in sensor networks

Daniel J. Abadi, Samuel Madden, Wolfgang Lindner

August 2005 **Proceedings of the 31st international conference on Very large data bases VLDB '05**

**Publisher:** VLDB Endowment

Full text available: pdf(286.61 KB)

Additional Information: [full citation](#), [abstract](#), [references](#), [index terms](#)

This paper presents a set of algorithms for efficiently evaluating join queries over static data tables in sensor networks. We describe and evaluate three algorithms that take advantage of distributed join techniques. Our algorithms are capable of running in limited amounts of RAM, can distribute the storage burden over groups of nodes, and are tolerant to dropped packets and node failures. REED is thus suitable for a wide range of event-detection applications that traditional sensor network dat ...

## 10 Wireless ad hoc multicast routing with mobility prediction

Sung-Ju Lee, William Su, Mario Gerla  
August 2001 **Mobile Networks and Applications**, Volume 6 Issue 4

**Publisher:** Kluwer Academic Publishers

Full text available:  [pdf\(186.00 KB\)](#) Additional Information: [full citation](#), [abstract](#), [references](#), [citations](#), [index terms](#)

An ad hoc wireless network is an infrastructureless network composed of mobile hosts. The primary concerns in ad hoc networks are bandwidth limitations and unpredictable topology changes. Thus, efficient utilization of routing packets and immediate recovery of route breaks are critical in routing and multicasting protocols. A multicast scheme, On-Demand Multicast Routing Protocol (ODMRP), has been recently proposed for mobile ad hoc networks. ODMRP is a reactive (on-demand) protocol that de ...

**Keywords:** ad hoc networks, mobile computing, mobility prediction, multicast and routing protocols

11 Mobility prediction and routing in *ad hoc* wireless networks

William Su, Sung-Ju Lee, Mario Gerla  
January 2001 **International Journal of Network Management**, Volume 11 Issue 1

**Publisher:** John Wiley & Sons, Inc.

Full text available:  [pdf\(405.80 KB\)](#) Additional Information: [full citation](#), [abstract](#), [references](#), [citations](#), [index terms](#)

By exploiting non-random behaviors for the mobility patterns that mobile users exhibit, we can predict the future state of network topology and perform route reconstruction proactively in a timely manner. Moreover, by using the predicted information on the network topology, we can eliminate transmissions of control packets otherwise needed to reconstruct the route and thus reduce overhead. In this paper, we propose various schemes to improve routing protocol performances by using mobility p ...

12 On parallel execution of multiple pipelined hash joins

 Hui-I Hsiao, Ming-Syan Chen, Philip S. Yu  
May 1994 **ACM SIGMOD Record , Proceedings of the 1994 ACM SIGMOD international conference on Management of data SIGMOD '94**, Volume 23 Issue 2

**Publisher:** ACM Press

Full text available:  [pdf\(1.24 MB\)](#) Additional Information: [full citation](#), [abstract](#), [references](#), [citations](#), [index terms](#)

In this paper we study parallel execution of multiple pipelined hash joins. Specifically, we deal with two issues, processor allocation and the use of hash filters, to improve parallel execution of hash joins. We first present a scheme to transform a bushy execution tree to an allocation tree, where each node denotes a pipeline. Then, processors are allocated to the nodes in the allocation tree based on the concept of synchronous execution time such that inner relations (i.e., hash tables) ...

13 Ad hoc multicast routing algorithm with swarm intelligence

Chien-Chung Shen, Chaiporn Jaikaeo  
February 2005 **Mobile Networks and Applications**, Volume 10 Issue 1-2

**Publisher:** Kluwer Academic Publishers

Full text available:  [pdf\(424.44 KB\)](#) Additional Information: [full citation](#), [abstract](#), [references](#), [index terms](#)

Swarm intelligence refers to complex behaviors that arise from very simple individual behaviors and interactions, which is often observed in nature, especially among social insects such as ants. Although each individual (an ant) has little intelligence and simply follows basic rules using local information obtained from the environment, such as ant's pheromone trail laying and following behavior, globally optimized behaviors, such as

finding a shortest path, emerge when they work collectively as ...

**Keywords:** ad hoc networks, multicast routing, swarm intelligence

#### 14 On zone-balancing of peer-to-peer networks: analysis of random node join

Xiaoming Wang, Yueping Zhang, Xiaofeng Li, Dmitri Loguinov

June 2004 **ACM SIGMETRICS Performance Evaluation Review , Proceedings of the joint international conference on Measurement and modeling of computer systems SIGMETRICS '04/Performance '04**, Volume 32 Issue 1

**Publisher:** ACM Press

Full text available: [pdf\(282.76 KB\)](#) Additional Information: [full citation](#), [abstract](#), [references](#), [citations](#), [index terms](#)

Balancing peer-to-peer graphs, including zone-size distributions, has recently become an important topic of peer-to-peer (P2P) research [1], [2], [6], [19], [31], [36]. To bring analytical understanding into the various peer-join mechanisms, we study how zone-balancing decisions made during the initial sampling of the peer space affect the resulting zone sizes and derive several asymptotic results for the maximum and minimum zone sizes that hold with high probability.

**Keywords:** balls-into-bins, load-balancing, modeling, peer-to-peer

#### 15 Chord: A scalable peer-to-peer lookup service for internet applications

Ion Stoica, Robert Morris, David Karger, M. Frans Kaashoek, Hari Balakrishnan

August 2001 **ACM SIGCOMM Computer Communication Review , Proceedings of the 2001 conference on Applications, technologies, architectures, and protocols for computer communications SIGCOMM '01**, Volume 31 Issue 4

**Publisher:** ACM Press

Full text available: [pdf\(205.73 KB\)](#) Additional Information: [full citation](#), [abstract](#), [references](#), [citations](#), [index terms](#)

A fundamental problem that confronts peer-to-peer applications is to efficiently locate the node that stores a particular data item. This paper presents *Chord*, a distributed lookup protocol that addresses this problem. Chord provides support for just one operation: given a key, it maps the key onto a node. Data location can be easily implemented on top of Chord by associating a key with each data item, and storing the key/data item pair at the node to which the key maps. Chord adapts effi ...

#### 16 Reusing invariants: a new strategy for correlated queries

Jun Rao, Kenneth A. Ross

June 1998 **ACM SIGMOD Record , Proceedings of the 1998 ACM SIGMOD international conference on Management of data SIGMOD '98**, Volume 27 Issue 2

**Publisher:** ACM Press

Full text available: [pdf\(1.55 MB\)](#) Additional Information: [full citation](#), [abstract](#), [references](#), [citations](#), [index terms](#)

Correlated queries are very common and important in decision support systems. Traditional nested iteration evaluation methods for such queries can be very time consuming. When they apply, query rewriting techniques have been shown to be much more efficient. But query rewriting is not always possible. When query rewriting does not apply, can we do something better than the traditional nested iteration methods? In this paper, we propose a new invariant technique to evaluate correlated queries ...

## 18 Storing and querying XML data using denormalized relational databases

Andrey Balmin, Yannis Papakonstantinou

March 2005 **The VLDB Journal — The International Journal on Very Large Data Bases**, Volume 14 Issue 1

**Publisher:** Springer-Verlag New York, Inc.

Full text available:  [pdf\(397.97 KB\)](#)

Additional Information: [full citation](#), [abstract](#)

XML database systems emerge as a result of the acceptance of the XML data model. Recent works have followed the promising approach of building XML database management systems on underlying RDBMS's. Achieving query processing performance reduces to two questions: (i) How should the XML data be decomposed into data that are stored in the RDBMS? (ii) How should the XML query be translated into an efficient plan that sends one or more SQL queries to the underlying RDBMS and combines the data ...

## 19 Industrial sessions: big data: Automating physical database design in a parallel database

Jun Rao, Chun Zhang, Nimrod Megiddo, Guy Lohman

June 2002 **Proceedings of the 2002 ACM SIGMOD international conference on Management of data SIGMOD '02**

**Publisher:** ACM Press

Full text available:  [pdf\(1.38 MB\)](#)

Additional Information: [full citation](#), [abstract](#), [references](#), [citations](#), [index terms](#)

Physical database design is important for query performance in a shared-nothing parallel database system, in which data is horizontally partitioned among multiple independent nodes. We seek to automate the process of data partitioning. Given a workload of SQL statements, we seek to determine automatically how to partition the base data across multiple nodes to achieve overall optimal (or close to optimal) performance for that workload. Previous attempts use heuristic rules to make those decision ...

## 20 R2-E: cross layer designs and protocols symposium: A distributed P2P network based on increasing reliability and scalability for internet applications

Ben-Jye Chang, Chao-Shu Chen, Ying-Hsin Liang, Hong-Da Lin

July 2006 **Proceeding of the 2006 international conference on Communications and mobile computing IWCMC '06**

**Publisher:** ACM Press

Full text available:  [pdf\(2.12 MB\)](#)

Additional Information: [full citation](#), [abstract](#), [references](#), [index terms](#)

In this paper, we propose an efficient, distributed, reliable P2P networks for this purpose, which is called hand-in-hand (HIH) P2P network. First, HIH adopts distributed index servers with unique individual ID as logical ring nodes for storing and managing the file sharing information. Second, HIH adopts a consistent hashing to hash the sharing

filename as a seed and maps the seed to a corresponding index server. The consistent hashing achieves some advantages including, scalable, providing a f ...

### 1 [Fast detection of communication patterns in distributed executions](#)

Thomas Kunz, Michiel F. H. Seuren

 November 1997 **Proceedings of the 1997 conference of the Centre for Advanced Studies on Collaborative research**
**Publisher:** IBM Press

Full text available: pdf(4.21 MB)

 Additional Information: [full citation](#), [abstract](#), [references](#), [index terms](#)

Understanding distributed applications is a tedious and difficult task. Visualizations based on process-time diagrams are often used to obtain a better understanding of the execution of the application. The visualization tool we use is Poet, an event tracer developed at the University of Waterloo. However, these diagrams are often very complex and do not provide the user with the desired overview of the application. In our experience, such tools display repeated occurrences of non-trivial commun ...

### 2 [From VHDL to efficient and first-time-right designs: a formal approach](#)

Peter F. A. Middelhoeck, Sreeranga P. Rajan

 April 1996 **ACM Transactions on Design Automation of Electronic Systems (TODAES)**, Volume 1 Issue 2

**Publisher:** ACM Press

Full text available: pdf(722.99 KB)

 Additional Information: [full citation](#), [abstract](#), [references](#), [citations](#), [index terms](#)

In this article we provide a practical transformational approach to the synthesis of correct synchronous digital hardware designs from high-level specifications. We do this while taking into account the complete life cycle of a design from early prototype to full custom implementation. Besides time-to-market, both flexibility with respect to target architecture and efficiency issues are addressed by the methodology. The utilization of user-selected behavior-preserving transformation steps e ...

### 3 [GPGPU: general purpose computation on graphics hardware](#)

David Luebke, Mark Harris, Jens Krüger, Tim Purcell, Naga Govindaraju, Ian Buck, Cliff Woolley, Aaron Lefohn

 August 2004 **Proceedings of the conference on SIGGRAPH 2004 course notes SIGGRAPH '04**

**Publisher:** ACM Press

Full text available:  [pdf\(63.03 MB\)](#) Additional Information: [full citation](#), [abstract](#)

The graphics processor (GPU) on today's commodity video cards has evolved into an extremely powerful and flexible processor. The latest graphics architectures provide tremendous memory bandwidth and computational horsepower, with fully programmable vertex and pixel processing units that support vector operations up to full IEEE floating point precision. High level languages have emerged for graphics hardware, making this computational power accessible. Architecturally, GPUs are highly parallel s ...

4 Link and channel measurement: A simple mechanism for capturing and replaying wireless channels

Glenn Judd, Peter Steenkiste

August 2005 **Proceeding of the 2005 ACM SIGCOMM workshop on Experimental approaches to wireless network design and analysis E-WIND '05**

**Publisher:** ACM Press

Full text available:  [pdf\(6.06 MB\)](#) Additional Information: [full citation](#), [abstract](#), [references](#), [index terms](#)

Physical layer wireless network emulation has the potential to be a powerful experimental tool. An important challenge in physical emulation, and traditional simulation, is to accurately model the wireless channel. In this paper we examine the possibility of using on-card signal strength measurements to capture wireless channel traces. A key advantage of this approach is the simplicity and ubiquity with which these measurements can be obtained since virtually all wireless devices provide the req ...

5 W1-A: medium access control #1: MAPT: network address and port translation approach to IP multicast and its application to public wireless LANs

Ryo Kitahara, Hidetoshi Ueno, Hideharu Suzuki, Norihiro Ishikawa, Takaaki Komura, Kenji Fujikawa, Haruo Takagi

July 2006 **Proceeding of the 2006 international conference on Communications and mobile computing IWCMC '06**

**Publisher:** ACM Press

Full text available:  [pdf\(412.31 KB\)](#) Additional Information: [full citation](#), [abstract](#), [references](#), [index terms](#)

IP Multicast has attracted a lot of attention as a cost-effective data delivery technique for music and video broadcasting services. Unfortunately, because most Internet Service Providers don't support IP multicast routing, end-to-end IP multicast is not well supported by the Internet. Therefore we propose a multicast routing method called MAPT (Multicast Address and a port Translation) which uses an address translation technique that converts IP addresses and UDP port numbers. We also propose a ...

7 Phoenix: a parallel programming model for accommodating dynamically joining/leaving resources

Kenjiro Taura, Kenji Kaneda, Toshio Endo, Akinori Yonezawa

June 2003 **ACM SIGPLAN Notices , Proceedings of the ninth ACM SIGPLAN symposium on Principles and practice of parallel programming PPOPP '03**, Volume 38 Issue 10

**Publisher:** ACM Press

Full text available: [pdf\(197.86 KB\)](#) Additional Information: [full citation](#), [abstract](#), [references](#), [index terms](#)

This paper proposes Phoenix, a programming model for writing parallel and distributed applications that accommodate dynamically joining/leaving compute resources. In the proposed model, nodes involved in an application see a large and fixed *virtual node name space*. They communicate via messages, whose destinations are specified by virtual node names, rather than names bound to a physical resource. We describe Phoenix API and show how it allows a transparent migration of application states ...

**Keywords:** distributed programming, message passing, migration, parallel programming, resource reconfiguration

8 Level set and PDE methods for computer graphics

David Breen, Ron Fedkiw, Ken Museth, Stanley Osher, Guillermo Sapiro, Ross Whitaker

August 2004 **Proceedings of the conference on SIGGRAPH 2004 course notes SIGGRAPH '04**

**Publisher:** ACM Press

Full text available: [pdf\(17.07 MB\)](#) Additional Information: [full citation](#), [abstract](#), [citations](#)

Level set methods, an important class of partial differential equation (PDE) methods, define dynamic surfaces implicitly as the level set (iso-surface) of a sampled, evolving nD function. The course begins with preparatory material that introduces the concept of using partial differential equations to solve problems in computer graphics, geometric modeling and computer vision. This will include the structure and behavior of several different types of differential equations, e.g. the level set eq ...

9 Building a scaleable geo-spatial DBMS: technology, implementation, and evaluation

Jignesh Patel, JieBing Yu, Navin Kabra, Kristin Tufte, Biswadeep Nag, Josef Burger, Nancy Hall, Karthikeyan Ramasamy, Roger Lueder, Curt Ellmann, Jim Kupsch, Shelly Guo, Johan Larson, David De Witt, Jeffrey Naughton

June 1997 **ACM SIGMOD Record , Proceedings of the 1997 ACM SIGMOD international conference on Management of data SIGMOD '97**, Volume 26 Issue 2

**Publisher:** ACM Press

Full text available: [pdf\(1.58 MB\)](#) Additional Information: [full citation](#), [abstract](#), [references](#), [citations](#), [index terms](#)

This paper presents a number of new techniques for parallelizing geo-spatial database systems and discusses their implementation in the Paradise object-relational database system. The effectiveness of these techniques is demonstrated using a variety of complex geo-spatial queries over a 120 GB global geo-spatial data set.

**10 Field programmable port extender (FPX) for distributed routing and queuing**

 John W. Lockwood, Jon S. Turner, David E. Taylor  
February 2000 **Proceedings of the 2000 ACM/SIGDA eighth international symposium on Field programmable gate arrays**

**Publisher:** ACM Press

Full text available:  [pdf\(709.83 KB\)](#) Additional Information: [full citation](#), [abstract](#), [references](#), [citations](#), [index terms](#)

Field Programmable Gate Arrays (FPGAs) are being used to provide fast Internet Protocol (IP) packet routing and advanced queuing in a highly scalable network switch. A new module, called the Field-programmable Port Extender (FPX), is being built to augment the Washington University Gigabit Switch (WUGS) with reprogrammable logic. FPX modules reside at the edge of the WUGS switching fabric. Physically, the module is inserted between an optical line card and the WUGS gigabit switch ...

**11 Parallelism in relational data base systems: architectural issues and design approaches**

 Hamid Pirahesh, C. Mohan, Josephine Cheng, T. S. Liu, Pat Selinger  
July 1990 **Proceedings of the second international symposium on Databases in parallel and distributed systems**

**Publisher:** ACM Press

Full text available:  [pdf\(2.50 MB\)](#) Additional Information: [full citation](#), [abstract](#), [references](#), [citations](#), [index terms](#)

With current systems, some important complex queries may take days to complete because of: (1) the volume of data to be processed, (2) limited aggregate resources. Introducing parallelism addresses the first problem. Cheaper, but powerful computing resources solve the second problem. According to a survey by Brodie,<sup>1</sup> only 10% of computerized data is in data bases. This is an argument for both more variety and volume of data to be moved into data base systems. We conject ...

**12 Distributed last call optimization for portable parallel logic programming**

 Balkrishna Ramkumar  
September 1992 **ACM Letters on Programming Languages and Systems (LOPLAS)**,  
Volume 1 Issue 3

**Publisher:** ACM Press

Full text available:  [pdf\(1.21 MB\)](#) Additional Information: [full citation](#), [abstract](#), [references](#), [index terms](#), [review](#)

A difficult but challenging problem is the efficient exploitation of AND and OR parallelism in logic programs without making any assumptions about the underlying target machine (s). In earlier papers, we described the design of a binding environment for AND and OR parallel execution of logic programs on shared and nonshared memory machines and the performance of a compiler (called ROLOG) using this binding environment on a range of MIMD parallel machines. In this paper, we present ...

**Keywords:** compiler optimizations, parallel logic programming

**13 The elements of nature: interactive and realistic techniques**

 Oliver Deussen, David S. Ebert, Ron Fedkiw, F. Kenton Musgrave, Przemyslaw Prusinkiewicz, Doug Roble, Jos Stam, Jerry Tessendorf  
August 2004 **Proceedings of the conference on SIGGRAPH 2004 course notes SIGGRAPH '04**

**Publisher:** ACM Press

Full text available:  [pdf\(17.65 MB\)](#) Additional Information: [full citation](#), [abstract](#)

This updated course on simulating natural phenomena will cover the latest research and

production techniques for simulating most of the elements of nature. The presenters will provide movie production, interactive simulation, and research perspectives on the difficult task of photorealistic modeling, rendering, and animation of natural phenomena. The course offers a nice balance of the latest interactive graphics hardware-based simulation techniques and the latest physics-based simulation techni ...

##### processing for DB2

Vanja Josifovski, Peter Schwarz, Laura Haas, Eileen Lin

June 2002 **Proceedings of the 2002 ACM SIGMOD international conference on Management of data SIGMOD '02**

**Publisher:** ACM Press

Full text available: pdf(1.05 MB)

Additional Information: [full citation](#), [abstract](#), [references](#), [citations](#), [index terms](#)

In a large modern enterprise, information is almost inevitably distributed among several database management systems. Despite considerable attention from the research community, relatively few commercial systems have attempted to address this issue. This paper describes new technology that enables clients of IBM's DB2 Universal Database to access the data and specialized computational capabilities of a wide range of non-relational data sources. This technology, based on the Garlic prototype deve ...

#### 15 Parallel execution of prolog programs: a survey

Gopal Gupta, Enrico Pontelli, Khayri A.M. Ali, Mats Carlsson, Manuel V. Hermenegildo

July 2001 **ACM Transactions on Programming Languages and Systems (TOPLAS)**, Volume 23 Issue 4

**Publisher:** ACM Press

Full text available: pdf(1.95 MB)

Additional Information: [full citation](#), [abstract](#), [references](#), [citations](#), [index terms](#)

Since the early days of logic programming, researchers in the field realized the potential for exploitation of parallelism present in the execution of logic programs. Their high-level nature, the presence of nondeterminism, and their referential transparency, among other characteristics, make logic programs interesting candidates for obtaining speedups through parallel execution. At the same time, the fact that the typical applications of logic programming frequently involve irregular computatio ...

**Keywords:** Automatic parallelization, constraint programming, logic programming, parallelism, prolog

#### 16 Response Time Analysis of Multiprocessor Computers for Database Support

Roger K. Shultz, Roy J. Zingg

March 1984 **ACM Transactions on Database Systems (TODS)**, Volume 9 Issue 1

**Publisher:** ACM Press

Full text available: pdf(2.27 MB)

Additional Information: [full citation](#), [abstract](#), [references](#), [citations](#), [index terms](#)

Comparison of three multiprocessor computer architectures for database support is made possible through evaluation of response time expressions. These expressions are derived by parameterizing algorithms performed by each machine to execute a relational algebra query. Parameters represent properties of the database and components of the machines. Studies of particular parameter values exhibit response times for conventional machine technology, for low selectivity, high duplicate occurrence, ...

#### 17 Collision detection and proximity queries

Sunil Hadap, Dave Eberle, Pascal Volino, Ming C. Lin, Stephane Redon, Christer Ericson

August 2004 **Proceedings of the conference on SIGGRAPH 2004 course notes**  
**SIGGRAPH '04**

**Publisher:** ACM Press

Full text available: pdf(11.22 MB) Additional Information: [full citation](#), [abstract](#)

This course will primarily cover widely accepted and proved methodologies in collision detection. In addition more advanced or recent topics such as continuous collision detection, ADFs, and using graphics hardware will be introduced. When appropriate the methods discussed will be tied to familiar applications such as rigid body and cloth simulation, and will be compared. The course is a good overview for those developing applications in physically based modeling, VR, haptics, and robotics.

18 **A robust protocol for parallel join operation in distributed data bases**

S. Bandyopadhyay, A. Sengupta

January 2000 **Proceedings of the first international symposium on Databases in parallel and distributed systems**

**Publisher:** IEEE Computer Society Press

Full text available: pdf(1.23 MB) Additional Information: [full citation](#), [abstract](#), [references](#), [citations](#), [index terms](#)

Fault tolerant distributed databases use replicated data(e.g., record or relation) to handle failures of one or more nodes in a computer network. Efficient and economic access strategies for such data bases have not been investigated. In this paper, the binary hypercube, a popular model for fault tolerant interconnection networks, has been studied. It has been shown that, for a local area network based on a binary hypercube, having 2r nodes where every data is replicate ...

19 **Implementation of a portable software DSM in Java**

Yukihiko Sohda, Hidemoto Nakada, Satoshi Matsuoka

June 2001 **Proceedings of the 2001 joint ACM-ISCOPE conference on Java Grande**

**Publisher:** ACM Press

Full text available: pdf(896.77 KB) Additional Information: [full citation](#), [abstract](#), [references](#), [index terms](#)

Rapid commoditization of advanced hardware and progress of networking technology is now making wide area high-performance computing a.k.a. the 'Grid' Computing a reality. Since a Grid will consist of vastly heterogeneous sets of compute nodes, especially commodity clusters, some have articulated the use of Java as a suitable technology to satisfy portability across different machines. Since Java's natural model parallelism is shared memory multithreading, one will have to support distributed ...

20 **A scalable content-addressable network**

Sylvia Ratnasamy, Paul Francis, Mark Handley, Richard Karp, Scott Schenker

August 2001 **ACM SIGCOMM Computer Communication Review , Proceedings of the 2001 conference on Applications, technologies, architectures, and protocols for computer communications SIGCOMM '01**, Volume 31 Issue 4

**Publisher:** ACM Press

Full text available: pdf(155.64 KB) Additional Information: [full citation](#), [abstract](#), [references](#), [citations](#), [index terms](#)

Hash tables - which map "keys" onto "values" - are an essential building block in modern software systems. We believe a similar functionality would be equally valuable to large distributed systems. In this paper, we introduce the concept of a Content-Addressable Network (CAN) as a distributed infrastructure that provides hash table-like functionality on Internet-like scales. The CAN is scalable, fault-tolerant and completely self-organizing, and we demonstrate its scalability, robustness and low ...
